Cross-country determinants of mergers and acquisitions ☆

Stefano Rossi, Paolo F. Volpin*

London Business School, Regent's Park, London NW1 4SA, UK

Abstract

We study the determinants of mergers and acquisitions around the world by focusing on differences in laws and regulation across countries. We find that the volume of M&A activity is significantly larger in countries with better accounting standards and stronger shareholder protection. The probability of an all-cash bid decreases with the level of shareholder protection in the acquirer country. In cross-border deals, targets are typically from countries with poorer investor protection than their acquirers' countries, suggesting that cross-border transactions play a governance role by improving the degree of investor protection within target firms.

1. Introduction

In a perfect world, corporate assets would be channelled toward their best possible use. Mergers and acquisitions (M&A) help this process by reallocating control over companies. However, frictions such as transaction costs, information asymmetries, and agency conflicts can prevent efficient transfers of control. Recent studies on corporate governance employ measures of the quality of the legal and regulatory environment within a country as proxies for some of these frictions, and show that differences in laws, regulation, and enforcement correlate with the development of capital markets, the ownership structure of firms, and the cost of capital (see, e.g., La Porta et al., 1997, 1998; Bhattacharya and Daouk, 2002).

In this paper we analyze a sample of mergers and acquisitions announced in the 1990s and completed by the end of 2002. Our sample comprises firms in 49 major countries and shows that differences in laws and enforcement explain the intensity and the pattern of mergers and acquisitions around the world. The volume of M&A activity is significantly larger in countries with better accounting standards and stronger shareholder protection. This result holds for several measures of M&A activity, and also when we control for other characteristics of the regulatory environment such as antitrust legislation and takeover laws. Our findings indicate that a more active market for mergers and acquisitions is the outcome of a corporate governance regime with stronger investor protection. We also show that hostile deals are relatively more likely in countries with better shareholder protection. One explanation is that good protection for minority shareholders makes control more contestable by reducing the private benefits of control.

Next, we provide evidence on cross-border mergers and acquisitions. We show that the probability that a given deal is cross-border rather than domestic decreases with the investor protection of the target's country. Even after we control for bilateral trade, relative GNP per capita, and cultural and geographical differences, we find that targets are typically from countries with poorer investor protection compared to their acquirers. This result suggests that cross-border M&A activity is an important channel for effective worldwide convergence in corporate governance standards, as argued by Coffee (1999).

Selling to a foreign firm is a form of contractual convergence similar to the decision to list in countries with better corporate governance and better-developed capital markets. Pagano et al. (2002) and Reese and Weisbach (2002) show that firms from countries with weak legal protection for minority shareholders list abroad more frequently than do firms from other countries. We show that firms in countries with weaker investor protection are often sold to buyers from countries with stronger investor protection.

We also analyze the determinants of the takeover premium and the method of payment in individual transactions. We show that the premium is higher in countries with higher shareholder protection, although this result is driven by deals with US and British targets. We find that the probability of an all-cash bid decreases with the degree of shareholder protection in the acquirer country, indicating that acquisitions paid with stock require an environment with high shareholder protection.

Our paper belongs to the growing literature exploring cross-country variation in governance structures around the world. Recent studies show that better legal protection of minority shareholders is associated with more developed stock markets (La Porta et al., 1997), higher valuation (La Porta et al., 2002), greater dividend payouts (La Porta et al., 2000b), lower concentration of ownership and control (La Porta et al., 1999), lower private benefits of control (Dyck and Zingales, 2004; Nenova, 2003), lower earnings management (Leuz et al., 2003), lower cash balances (Dittmar et al., 2003), and higher correlation between investment opportunities and actual investments (Wurgler, 2000). Our paper shows that better investor protection is correlated with a more active market for mergers and acquisitions.

We structure the paper as follows. Section 2 describes the data. Section 3 contains the analyses of the determinants of M&A activity. Section 4 discusses the main results. Section 5 concludes.

2. Data

Our sample contains all mergers and acquisitions announced between January 1, 1990 and December 31, 1999, completed as of December 31, 2002, and reported by SDC Platinum, a database from Thomson Financial. Because we wish to study transactions clearly motivated by changes in control, we focus on mergers (business combinations in which the number of companies decreases after the transaction) and acquisitions of majority interests (when the acquirer owns less than 50% of the target company's stock before the deal, and more than 50% after the deal). A second reason for this sample selection is that the coverage of transfers of minority stakes (below 50%) is likely to be severely affected by cross-country differences in disclosure requirements. By selecting only transfers of stakes above 50%, we minimize these disclosure biases. However, in interpreting the results, we note that the availability and quality of the data might be better in some countries (such as the US and UK) because of broader SDC coverage. A related concern is that the coverage of small countries improves over time. To address this concern, we replicate our analysis on the subsample of deals announced in the second half of the 1990s and find similar results.

The availability of empirical measures of investor protection limits our set to 49 countries. The sample from SDC includes 45,686 deals, 22% of which have a traded company as the target. Excluded deals represent about 6% of the original dataset in number and 1% in value.

The appendix describes the variables we use in this paper and indicates their sources. These variables can be classified into three broad categories corresponding to three different levels of analysis. The first set of variables is at the country level. It includes measures of M&A activity from the target's perspective, as well as broad macroeconomic conditions and proxies for the legal and regulatory environment. We use these variables in our cross-country analysis of the determinants of international mergers and acquisitions. Our second category of variables measures the flow of M&A activity and cultural differences and similarities between any ordered pairs of

acquirer and target countries (there are 49×48 or 2,352 ordered pairs). The third set of variables is at the individual deal level and includes data on the premium paid, the value of the deal, and the means of payment. We use these data, together with the country-level variables defined above, in our analysis of the determinants of the premium and the means of payment.

2.1. M&A activity

Tables 1 and 2 show the data on M&A activity sorted by target country. We define volume as the percentage of traded firms that are targets of successful mergers or acquisitions. We interpret this variable as a measure of the ability of an economy to reallocate control over corporate assets. We also use other measures of volume, such as the total number of completed deals divided by population, the value of all completed deals divided by GDP, and the value of completed deals among traded companies divided by stock market capitalization. The qualitative results do not change. As is apparent from Table 1, the market for corporate control plays a different role in different countries. For example, volume is very low in Japan (only 6.4% of Japanese traded companies are targets of a completed deal during the 1990s) and very high in the US (65.6% of US traded companies are targets in a completed deal). The table also shows some similarities across countries. For example, volume in France, Italy, and the United Kingdom is similar, although their governance regimes are quite different.

Of all mergers and acquisitions, we focus on hostile deals, since they are likely to play an important governance role. We examine the number of attempted hostile takeovers as a percentage of the total number of traded companies. The intuition is that the disciplinary role of hostile takeovers is related to the threat they represent to incumbent managers. In other words, it is likely that attempted (but failed) hostile takeovers play just as important a role in disciplining management as hostile takeovers that are eventually completed.

In all countries, the frequency of hostile takeovers is very small. According to SDC, they are absent in 21 out of 49 countries, and when present they never exceed the 6.44% observed in the United States. Therefore, according to SDC Platinum, hostile takeovers are rare. However, this conclusion could be unwarranted, because our source might fail to record all unsuccessful takeovers. Moreover, in some countries the corporate governance role of hostile takeovers could be performed by hostile stakes, as Jenkinson and Ljungqvist (2001) show for Germany.

We define the cross-border ratio as the percentage of completed deals in which the acquirer is from a different country than the target. In the case of mergers, we follow our data source to distinguish acquirers from targets. For example, in the merger between Daimler and Chrysler, Thomson codifies Daimler as the acquirer and Chrysler as the target.

The number of cross-border mergers and acquisitions is 11,638, corresponding to 25% of the total. Table 1 shows that different countries play different roles in the cross-border M&A market. For instance, 51% of the acquirers in Mexican deals are foreign, compared to only 9.1% in the United States.

Table 1
Data on international mergers and acquisitions sorted by target country
Volume is the percentage of traded companies targeted in a completed deal. Hostile takeover is the number of attempted hostile takeovers as a percentage of domestic traded firms. Cross-border ratio is the number of cross-border deals as a percentage of all completed deals.

To study the cross-country variations in the premiums and means of payment, we use transaction-level data. The premium is the bid price as a percentage of the closing price four weeks before the announcement. We characterize the means of payment of an individual deal with a dummy variable that equals one if the acquisition is entirely

paid in cash, and zero otherwise. We compute these variables using data available from SDC Platinum. After excluding deals with incomplete information, we have 4,007 observations from 35 countries.

As shown in Table 2, the data are highly concentrated: the target is a US firm in 60% of the sample and a UK firm in 15% of the sample. The bid price ranges from 99.6% of the pre-announcement price (in Japan) to 227.1% (in Indonesia). In Italy, 88% of the acquisitions of Italian targets are paid entirely in cash. In the US, only 37% of the deals are paid wholly in cash.

2.2. Investor protection

By reshuffling control over companies, mergers and acquisitions help allocate corporate assets to their best possible use. Investor protection can affect the volume of mergers and acquisitions because it affects the magnitude of frictions and inefficiencies in the target country. As proxies for investor protection, we use several indexes developed by La Porta et al. (1998): an index of the quality of the accounting standards, an index of shareholder protection that combines an index of the quality of law enforcement (rule of law) and an index of the rights that shareholders have with respect to management (antidirector rights), and a dummy variable for common-law countries. These indexes are highly correlated (their pair-wise correlations range between 40% and 60%) because they all reflect to some degree the underlying quality of investor protection in a country. However, they measure different institutional characteristics.

Accounting standards measure the quality of the disclosure of accounting information. The accounting standards quality index is created by the Center for International Financial Analysis and Research and rates the 1990 annual reports of at least three firms in every country on their inclusion or omission of 90 items. Thus, each country obtains a score out of 90, with a higher number indicating more disclosure. This variable affects M&A activity because good disclosure is a necessary condition for identifying potential targets. Accounting standards also reflect corporate governance, because they reduce the scope for expropriation by making corporate accounts more transparent.

Our second measure is an index of shareholder protection that ranges between zero and six. It captures the effective rights of minority shareholders with respect to managers and directors and is defined as an antidirector rights index multiplied by a rule of law index and divided by ten. When minority shareholders have fewer rights, they are more likely to be expropriated. As a consequence, the stock market is less developed, and raising external equity, particularly to finance a takeover, is more expensive. At the same time, with low shareholder protection, the private benefits of control are high and the market for corporate control is relatively less effective, because incumbents will try to entrench themselves via ownership concentration and takeover deterrence measures (Bebchuk, 1999).

The common law measure is a dummy variable that equals one if the origin of the company law is the English common law, and zero otherwise. La Porta et al. (1998) argue that legal origin is a broad indicator of investor protection and show that

countries with common law as the legal origin better protect minority shareholders than do countries with civil law as the legal origin. Although common law should not directly affect mergers and acquisitions, we include this variable because it is correlated with other proxies of investor protection and is truly exogenous. Hence, it is a good instrument for investor protection.

We note that the number of observations in our empirical analysis varies with the measure of investor protection used, because accounting standards are not available for Ecuador, Indonesia, Ireland, Jordan, Kenya, Pakistan, Sri Lanka, and Zimbabwe.

3. Determinants of M&A activity

We examine five dimensions of mergers and acquisitions: the volume, the incidence of hostile takeovers, the pattern of cross-border deals, the premium, and the method of payment.

3.1. Volume

We start with the relation between the volume of M&A activity and investor protection at the target-country level. Our specification is

$$\text{Volume} = \alpha + \beta X + \gamma \text{ investor protection} + \varepsilon, \tag{1}$$

where the dependent variable, volume, is the percentage of traded firms that are targets of successful mergers or acquisitions. The variables for common law, accounting standards, and shareholder protection are proxies for investor protection. Control factors (X) in all specifications are GDP growth, which proxies for the change in economic conditions, and the logarithm of the 1995 per capita GNP, which proxies for the country's wealth.

Table 3 reports the coefficients of six Tobit models derived from specification (1). We estimate Tobit models because the dependent variable (volume) is bounded between zero and 100 by construction. Column 1 shows that the frequency of mergers among traded companies is 7.5% higher in common-law countries than in civil-law countries. The results in Column 2 show that accounting standards are positively and significant correlated with volume. A 12-point increase in the accounting standards measure (from the quality of accounting standards in Italy to that in Canada) correlates with a 5% increase in the volume of mergers and acquisitions. Column 3 finds a similar result for shareholder protection. A one-point increase in shareholder protection (for instance, the adoption of voting by mail in a country like Belgium) is associated with 4% more volume. Thus, we find that there are more mergers and acquisitions in countries with better investor protection. We note that a one-point increase in the index of antidirector rights (such as the adoption of voting by mail) translates into a one-point increase in shareholder protection only in a country like Belgium, which also scores ten in the index of rule of law. In a country like Italy, which scores 8.33 in the index of rule of law, the same

Table 3

Determinants of the volume across countries

The table presents the results of six Tobit models estimated by maximum likelihood for the sample of 49 target countries. The dependent variable is volume, the percentage of traded companies targeted in a completed deal. The independent variables are: common law, a dummy variable that equals one if the origin of the company law is the English common law, and zero otherwise; accounting standards, an index of the quality of accounting disclosure; shareholder protection, a measure of the effective rights of minority shareholders; ownership concentration, the average equity stake owned by the three largest shareholders in the ten largest nonfinancial domestic firms in 1994; mandatory bid rule, a dummy variable that equals one if acquirers are forced to make a tender offer to all shareholders when passing a given ownership threshold, and zero otherwise; market return, the average annual stock market return in the 1990s; and market dominance, a survey-based measure of product market concentration. The logarithm of GNP per capita and GDP growth are included in all regressions as control variables. Standard errors are shown in parentheses.

***, **, * indicate significance at 1% percent, 5%, and 10% levels, respectively.

change in minority shareholders' rights implies only a 0.833-point increase in shareholder protection.

In Column 4, we estimate a joint regression with accounting standards and shareholder protection and find that only the former is statistically significant. This result suggests that disclosure rules are more relevant for takeovers than are shareholder rights. In Column 5, we add ownership concentration, which is potentially an important explanatory variable. Ownership concentration in a country is the average equity stake owned by the three largest shareholders in the ten largest nonfinancial domestic firms in 1994, from La Porta et al. (1998). We find

that, as in the individual regressions, the coefficients on accounting standards and shareholder protection are positive and significant. The coefficient on ownership concentration is also positive and significant. This finding indicates that, when we control for investor protection, countries with more concentrated ownership have more mergers and acquisitions. This result is consistent with Shleifer and Vishny (1986), who argue that transfers of control are easier in companies with more concentrated ownership structure because they overcome the free-rider problem in takeovers.

The results in Column 5 help explain why shareholder protection is not significant in Column 4. On the one hand, shareholder protection reduces the costs of raising external equity, thereby increasing the volume of mergers. On the other hand, it decreases ownership concentration, which makes friendly transfers of control less likely. By controlling for ownership concentration, we are able to disentangle the two effects.

In Column 6, we evaluate the robustness of the results on investor protection by adding further control variables to capture cross-country differences in the regulatory environment. We show the results only with the common law variable as our proxy for investor protection, although we obtain similar results for accounting standards and shareholder protection. A mandatory bid rule, which we capture with a dummy variable that equals one if acquirers are forced to make a tender offer to all shareholders when passing a given ownership threshold and zero otherwise, might reduce the volume of mergers and acquisitions because it imposes further costs on the potential bidder. The market return, calculated as the average annual stock market return during the 1990s, might affect M&A activity because of valuation waves (Shleifer and Vishny, 2003). However, there are two opposing effects when the stock market is booming. Targets could become too expensive, reducing the volume of deals, but acquirers enjoy low takeover costs because they can pay with more highly valued stock, leading to a high takeover volume. Market dominance, a measure of product market concentration in 1995 from the 1992 Global Competitiveness Report (published by the World Economic Forum), could reduce the volume because of lower availability of targets.

The results in Column 6 show that common law is still significant and its coefficient is virtually unchanged from Column 1. None of the control variables are statistically significant. Note that the number of observations decreases from 49 to 41 because market return is not available for Taiwan and Uruguay and market dominance is not available for Ecuador, Kenya, Nigeria, Pakistan, Sri Lanka, Uruguay, and Zimbabwe.

3.2. Hostile takeovers

Many financial economists argue that hostile takeovers play an important governance role (for instance, see Manne, 1965; Jensen, 1993; and Franks and Mayer, 1996). To analyze cross-country differences in the frequency of hostile takeovers, we estimate

$$\text{Hostile takeover} = \alpha + \beta X + \gamma \text{ investor protection} + \varepsilon, \tag{2}$$

Table 4
Incidence of hostile takeovers
The table presents the results of six Tobit models estimated by maximum likelihood on the sample of 49 target countries. The dependent variable is hostile takeover, or attempted hostile takeovers as a percentage of traded firms. The independent variables are: common law, a dummy variable that equals one if the origin of the company law is the English common law, and zero otherwise; accounting standards, an index of the quality of accounting disclosure; shareholder protection, a measure of the effective rights of minority shareholders; ownership concentration, the average equity stake owned by the three largest shareholders in the ten largest nonfinancial domestic firms in 1994; cross-border regulation, a dummy variable that equals one if foreign buyers need government approval, and zero otherwise; market return, the average annual stock market return in the 1990s; and mandatory bid rule, a dummy variable that equals one if acquirers are forced to make a tender offer to all shareholders when passing a given ownership threshold, and zero otherwise. The logarithm of GNP per capita and GDP growth are included in all regressions as control variables. Standard errors are shown in parentheses.

	(1)	(2)	(3)	(4)	(5)	(6)

***, **, * indicate significance at 1%, 5%, and 10% levels, respectively.

where the hostile takeover variable is the number of attempted hostile takeovers in the 1990s as a percentage of the number of domestic traded companies. Common law, accounting standards, shareholder protection, and ownership concentration are proxies for investor protection, as described in Section 2.2. We include GDP growth and the logarithm of GNP per capita as control factors in all specifications.

The results are presented in Table 4. The first three columns show that common law, accounting standards, and shareholder protection are positively and significantly correlated with hostile takeovers. To interpret these results, note that hostile takeovers require that control be contestable, a feature that is less common in countries with poorer investor protection.

Column 4 shows that shareholder protection dominates accounting standards. A one-point increase in shareholder protection (e.g., the introduction of voting by mail in Belgium) is associated with 0.8 percentage points more hostile takeovers. Shareholder protection makes control more contestable by reducing the private benefits of control.

In Column 5, we add ownership concentration as a control variable. This variable is not significant. It marginally reduces the coefficient on shareholder protection without affecting its statistical significance. This result compares with Table 3, in which ownership concentration is positive and significant. According to Shleifer and Vishny (1986), ownership concentration facilitates only friendly transfers of control, not hostile takeovers. Hence, the insignificant coefficient in Column 5 of Table 4 is not surprising.

To evaluate the robustness of the main result that hostile takeovers are more common in countries with better investor protection, in Column 6 we add some control variables to the specification in Column 1 to capture cross-country differences in the regulatory environment. As in Table 4, we control for mandatory bid rules and market returns. We also incorporate cross-border regulation with a dummy variable that equals one if a foreign buyer needs government approval before acquiring control of a domestic firm, and zero otherwise. Because of cultural differences, deals initiated by foreign bidders are more likely to be hostile. Hence, we expect cross-border regulation to reduce the frequency of hostile takeovers.

The results in Column 6 show that common law is significant and that its coefficient is virtually unchanged from Column 1. The frequency of attempted hostile takeovers among traded companies is 1.6% higher in common-law than in civil-law countries. Cross-border regulation is also significant and negative, as predicted. The requirement of government approval for foreign acquisitions reduces the frequency of attempted hostile takeovers by 1.8%. Market returns and mandatory bid rules are not statistically significant.

3.3. Cross-border mergers and acquisitions

La Porta et al. (2000a, p. 23) write that "When a British firm fully acquires a Swedish firm, the possibilities for legal expropriation of investor diminish. Because the controlling shareholders of the Swedish company are compensated in such a friendly deal for the lost private benefits of control, they are more likely to go along. By replacing the wasteful expropriation with publicly shared profits and dividends, such acquisitions enhance efficiency." This statement implies two testable hypotheses that we address in this section: first, the probability that a deal is cross-border rather than domestic is higher in countries with lower investor protection; and second, the acquirers in cross-border deals will come from countries that have higher investor protection than the targets' countries.

3.3.1. Target-country analysis

As before, we adapt specification (1) by changing the dependent variable

$$\text{Cross-border ratio} = \alpha + \beta X + \gamma \text{ investor protection} + \varepsilon, \tag{3}$$

where the cross-border ratio is the number of cross-border deals as a percentage of all completed deals by target country. Common law, accounting standards, and shareholder protection are our proxies for investor protection. We expect the cross-border ratio to decrease with investor protection. As before, we control for the logarithm of GNP per capita, as a measure of a country's wealth, and GDP growth as a proxy for the change in macroeconomic conditions.

Table 5 reports the coefficients of six Tobit models derived from specification (3). The results confirm our prediction: the probability that a completed deal is cross-border rather than domestic is higher in countries with lower investor protection. The coefficients on common law, accounting standards, and shareholder protection are all negative and significant at the 1% level. In economic terms, the probability that a completed deal is cross-border is 14.5% higher in civil-law than in common-law countries. Raising the accounting standards measure by 12 points (from Italy's to Canada's accounting standards) decreases cross-border deals by 5%. An increase in shareholder protection by one point (for instance, the adoption of voting by mail in Belgium) decreases the cross-border ratio by 4%. Ownership concentration, which we add in Column 5 as a control variable, is not statistically significant.

To evaluate the robustness of the results, in Column 6 we augment the specification in Column 1 with some control variables. We add cross-border regulation because we expect fewer cross-border deals when there are more regulatory requirements. We control for market returns because we expect fewer cross-border deals when the stock market is booming and the target firms' stocks are (potentially) overvalued. At the same time, this variable will not be significant if the acquirer's stock market is also thriving. We include openness, a measure of the cultural attitude towards cross-border deals (from the 1996 Global Competitiveness Report) because such deals are more likely if the country is friendlier to foreigners.[1] Our results show that common law is still significant and that its coefficient is unaffected. Openness is negative and significant, as predicted. The coefficients on market return and cross-border regulation are not significant.

3.3.2. Ordered-pair analysis

The results in Table 5 indicate that cross-border mergers and acquisitions play a governance role by targeting firms in countries with lower investor protection. To explore this hypothesis, we arrange our dataset to produce a worldwide matrix of (49×48) matched pairs. In these pairs, we define each entry, cross-border deals$_{s,b}$, as the number of deals in which the acquirer comes from country b (for buyer) and the target is in country s (for seller), as a percentage of the total number of deals in country s.

---

[1] Another potential determinant of international mergers and acquisitions is tax competition across countries. For instance, taxes can affect M&A activity if it is easier for domestic firms to take advantage of investment tax credits and accelerated depreciation in the target country than for foreign firms. Moreover, the tax treatment of foreign income differs across countries. However, we do not control for taxes in our study because the complexity of the issue requires a paper on its own.

Table 5

Cross-border versus domestic deals

The table presents the results of six Tobit models estimated by maximum likelihood on the sample of 49 target countries. The dependent variable is cross-border ratio, or cross-border deals as a percentage of all completed deals. The independent variables are: common law, a dummy variable that equals one if the origin of the company law is the English common law, and zero otherwise; accounting standards, an index of the quality of accounting disclosure; shareholder protection, a measure of the effective rights of minority shareholders; ownership concentration, the average equity stake owned by the three largest shareholders in the ten largest nonfinancial domestic firms in 1994; cross-border regulation, a dummy variable that equals one if foreign buyers need government approval, and zero otherwise; market return, the average annual stock market return in the 1990s; and openness, a survey-based measure of the cultural attitude towards cross-border deals. The logarithm of GNP per capita and GDP growth are included in all regressions as control variables. Standard errors are shown in parentheses.

***, **, * indicate significance at 1%, 5%, and 10% levels, respectively.

With the newly arranged dataset, we can study the pattern of cross-border mergers and acquisitions by simultaneously controlling for the characteristics of target and acquirer countries. The specification is

$$\text{Cross-border deals}_{s,b} = \beta X_{s,b} + \gamma \Delta \text{ (investor protection)}_{s,b} + \delta_b + \zeta_s + \varepsilon_{s,b}, \quad (4)$$

where the dependent variable is the number of cross-border deals in which the acquirer comes from country b and the target from country s ($b \neq s$) as a percentage of the total number of deals (cross-border and domestic) in country s. Our hypothesis is that the volume of cross-border M&A activity between country b (the

acquirer) and country s (the target) correlates positively with the difference in investor protection between the two countries. The proxies for investor protection are accounting standards and shareholder protection.

We note that our specification also includes fixed effects for target and acquirer countries. These fixed effects control for all cultural and institutional characteristics of the two countries, including the level of investor protection in the individual countries. We control for differences in the logarithm of GNP per capita of the acquirer and target countries as a measure of the relative economic development of the two countries. We also include two dummy variables equal to one if the acquirer and target share the same cultural background, that is, if they have the same official language and if they belong to the same geographical area.

Table 6 reports our results. In Columns 1 and 2, we include only one measure of investor protection per regression. We find that the volume of M&A activity between two countries is positively correlated with their difference in investor protection. This result means that acquirers typically come from countries with better accounting standards and stronger shareholder protection than the targets' countries.

In Column 3, we estimate the marginal impact of each variable by estimating a joint regression with the two measures. We find that only the difference in shareholder protection is statistically significant. On average, shareholder protection increases in the target company via the cross-border deal. This finding is consistent with the view that such acquisitions enhance efficiency because the increase in shareholder protection curbs the expropriation of minority shareholders and, therefore, reduces the cost of raising external equity. We also find that richer countries are more likely to be acquirers than targets, and that most cross-border deals happen between countries sharing the same language and geographical area.

In Column 4, we add the difference in market return between acquirer and target countries as a control variable. We would expect more deals when the acquirer's stock market is booming relatively to the target's stock market, but we find no such evidence.

A potentially important missing variable in the analysis is the volume of trade between two countries. In fact, companies that export to a given country might engage in M&A activity in that country for reasons that have nothing to do with governance. To control for this alternative explanation, in Column 5 we add bilateral trade to our regression. We define bilateral trade$_{s,b}$ as imports from country b to country s as a percentage of total imports of country s. Bilateral trade is not available for six countries: Belgium, Brazil, Israel, Nigeria, Switzerland and Zimbabwe. The number of observations in Column 5 changes accordingly. The results for shareholder protection are unchanged. The acquirer typically has stronger shareholder protection than the target. As we expected, bilateral trade is positive and significant, confirming that trade is an important motive for cross-border mergers and acquisitions. Same language and the difference in the logarithm of GNP per capita are no longer significant once bilateral trade is added to the baseline specification.

Table 6

The governance motive in cross-border M&A

The table presents the results of five OLS regressions for the sample of matched country pairs. The dependent variable is cross-border deals$_{s,b}$, or the number of cross-border deals where the target is from country s and the acquirer is from country b ($s \neq b$) as a percentage of the total number of deals in country s. The independent variables are the difference between acquirer and target countries' investor protection as measured alternatively by accounting standards, an index of the quality of accounting disclosure, and by shareholder protection, a measure of the effective rights of minority shareholders. We include as control variables the difference between the acquirer's and the target's logarithm of GNP per capita; same language, a dummy variable that equals one if the target and acquirer come from countries with the same official language, and zero otherwise; and same geographical area, a dummy variable that equals one if the target and acquirer come from the same geographical area. In Column 4, we add the difference between country b and country s in market return, the average annual stock market return in the 1990s. In Column 5, we add bilateral trade$_{s,b}$, the value of imports by country s from country b as a percentage of total imports by country s. The regressions contain fixed effects both for target and acquirer country (not shown). The standard errors shown in parentheses are adjusted for heteroskedasticity using Huber (1967) and White (1980) corrections.

***, **, * indicate significance at 1%, 5% and 10% levels, respectively.

3.4. Premium

We use the sample of individual transactions to analyze the cross-country determinants of the takeover premium. We estimate the specification

$$\text{Log (premium)} = \alpha + \beta X + \gamma \text{ shareholder protection} + \varepsilon, \tag{5}$$

where premium is the bid price as a percentage of the target's closing price four weeks before the announcement of the deal, shareholder protection is measured at the target country level, and X is a set of control factors. Control variables at the deal level are target size, the logarithm of the target's market capitalization four weeks before the announcement, a dummy variable (cross-border) that equals one if the

deal is cross-border and zero otherwise; a dummy variable (hostile bid) that equals one if the deal is hostile and zero otherwise; a dummy variable (tender offer) that equals one if the deal involves a tender offer and zero otherwise; and a dummy variable (contested bid) that equals one if the number of bidders is larger than one and zero otherwise.

Table 7 shows the results of six regressions based on specification (5). In all regressions, the standard errors shown in parentheses are adjusted for hetero-skedasticity, using the Huber (1967) and White (1980) corrections, and for clustering at the country level following Huber (1967). We correct for clustering because observations within a country are likely to be correlated with each other. We also include year and industry (at one-digit SIC-code level) dummies, but we do not report their coefficients.

In Column 1, we find that shareholder protection is positively correlated with the takeover premium. An increase in the level of shareholder protection by one point (e.g., the introduction of voting by mail in Belgium) is associated with a 0.04 increase in the logarithm of the premium, which translates into an average increase of 6% in the premium. Target size is negative and significant, that is, larger deals are associated with lower premiums.

In Column 2, we add the deal-level dummy variables for cross-border, hostile bid, tender offer, and contested bid. The result on shareholder protection does not change and the new controls are all positive, as expected. All but hostile bids are statistically significant. We interpret the finding on tender offers as evidence of the free-rider hypothesis: that is, the bidder in a tender offer needs to pay a higher premium to induce shareholders to tender their shares. This theory would also predict that the premium paid should be higher the more diffuse the target's ownership structure. However, we cannot test this hypothesis directly because we do not have data on ownership structure for individual target companies. Contested bids are associated with a 0.1 increase in the logarithm of the premium, which translates into an average premium increase of 15%, consistent with the view that competition for targets is associated with higher premiums. Cross-border deals are associated with a 0.03 increase in the logarithm of the premium, which translates into an average premium increase of 3%.

Our finding that takeover premiums are higher in countries with higher shareholder protection can be interpreted by noting that the takeover premium measures the gain available to all target shareholders. There are two reasons why the premium might be higher in countries with stronger shareholder protection. First, shareholder protection reduces the cost of capital and therefore increases (potential) competition among bidders and the premium paid by the winning bidder. Second, diffuse ownership is more common in countries with higher shareholder protection. In turn, diffuse ownership exacerbates the free-rider problem in takeovers by forcing bidders to pay a higher takeover premium than otherwise (Grossman and Hart, 1980).

A concern with this interpretation is the possibility that the premium measures the private benefits of control. To explore this issue, in Column 3 we add the difference between the acquirer and target countries' shareholder protection as a further

Table 7

Determinants of the takeover premium

The table presents the results of six OLS regressions for the sample of individual deals. The dependent variable is the natural logarithm of premium, or the bid price as a percentage of the closing price of the target four weeks before the announcement. Independent variables at the country level are shareholder protection, a measure of the effective rights of minority shareholders, and mandatory bid rule, a dummy variable that equals one if in 1995 there was a legal requirement to make a tender offer when shareholdings after the acquisition exceed a given ownership threshold, and zero otherwise. The control variable at the cross-country level is the difference between the acquirer and target countries' shareholder protection. Control variables at the deal level are: target size, the logarithm of the target's market capitalization four weeks before the announcement; cross-border, a dummy variable that equals one if the deal is cross-border, and zero otherwise; hostile bid, a dummy variable that equals one if the deal is hostile, and zero otherwise; tender offer, a dummy variable that equals one if the deal involves a tender offer, and zero otherwise; contested bid, a dummy variable that equals one if the number of bidders is larger than one, and zero otherwise; and bidder M/B, the equity market-to-book ratio of the bidder four weeks before the announcement. In all regressions, we also include year and industry (at one-digit SIC-code level) dummies (not shown). In Column 6 we add two dummy variables that identify deals where the target firm is from the US (US targets) and from the UK (UK targets), respectively. The standard errors (in parentheses) are adjusted for heteroskedasticity using Huber (1967) and White (1980) corrections and for clustering at country level using the Huber (1967) correction.

***, **, * indicate significance at 1%, 5%, and 10% levels, respectively.

control variable. If the premium measures the private benefits of control, we expect to find a negative and significant coefficient on this control variable, as in Dyck and Zingales (2004). The reason is that an acquirer coming from a country with lower shareholder protection is better able to extract private benefits of control than an acquirer coming from a country with stricter rules.

In Column 3, we find that the difference between acquirer and target countries' shareholder protection is not statistically significant. This result indicates that premium is not a proxy for the private benefits of control but for the total premium available to all shareholders. This finding also indicates that acquirers from countries with better shareholder protection do not need to pay more than acquirers from countries with weaker shareholder protection in cross-border deals.

According to Rau and Vermaelen (1998), glamour firms (as measured by high market-to-book ratios) will tend to overestimate their ability to create synergies in the target and should therefore be willing to pay more than managers of value firms (as measured by low market-to-book ratios). Therefore, in Column 4, we add the equity market-to-book ratio (M/B) of the bidder four weeks before the announcement. We obtain this information from Datastream. As a result of the matching procedure, the number of observations in Column 4 drops to 1,005. Contrary to the prediction, our results show that the bidder M/B is not correlated with the premium.

Comment and Schwert (1995) show that takeover laws are an important determinant of the takeover premium. Therefore, in Column 5 we control for differences in takeover laws across countries. The mandatory bid rule variable equals one if in 1995 there was a legal requirement to make a tender offer when shareholdings after the acquisition exceed a given ownership threshold, and zero otherwise. For instance, the mandatory bid variable rule equals one in the United Kingdom, where the threshold is 30%, and zero in the United States, where only a few states have a similar provision. We find a negative and significant coefficient for the mandatory bid rule, perhaps because a mandatory bid rule increases the cost of takeovers and therefore reduces competition among bidders. However, a mandatory bid rule might also increase the premium, because only high-premium takeovers that compensate the bidders for the high takeover costs succeed. To distinguish between the two effects, in an unreported regression we add the interactive term of mandatory bid rule multiplied by target size. The coefficient on this interactive term should measure the impact on the premium that is due to reduced competition, because larger deals are more likely to be deterred. The coefficient on the mandatory bid rule should reflect the fact that low-premium takeovers do not go through. We find that the coefficient on the mandatory bid rule is negative and significant, and that the coefficient on the interactive term is not significant. This result suggests that the mandatory bid rule variable captures an institutional difference across countries.

Because 75% of the deals have a US or UK target, in Column 6 we check the robustness of our findings by using two dummy variables that identify deals with US and UK targets, respectively. The results show that higher premiums are a feature of US and UK targets. The logarithm of the premium is 0.16 higher in the US and 0.09 higher in the UK than in the other countries. Note that the mandatory bid rule is no

longer significant. This finding suggests that the mandatory bid rule is significant in Column 5 only because it captures the difference between US and UK targets.

3.5. Means of payment

Legal protection of investors may also affect the means of payment used in mergers and acquisitions. In a country with low investor protection, target shareholders are likely to prefer cash over the bidder's equity as the takeover currency, due to the risk of expropriation for being minority shareholders. We therefore expect less equity financing and more cash financing in countries with lower shareholder protection.

We estimate the following regression for the method of payment:

$$\text{Prob (all-cash bid)} = \alpha + \beta X + \gamma \text{ shareholder protection} + \varepsilon. \tag{6}$$

In this regression, which is similar to Eq. (3), our control variables are the same as those in Table 6: target size, cross-border, hostile bid, tender offer, contested bid, bidder M/B, and mandatory bid rule. We expect that larger deals are less likely to be paid entirely with cash. Cross-border deals might more often be paid in cash because shareholders dislike receiving foreign stocks as compensation. To entice shareholders to tender, hostile bids, tender offers, and contested bids are likely to be in cash.

Table 8 reports the results of six regressions based on specification (6). In all regressions, the standard errors shown in parentheses are adjusted for heteroskedasticity using Huber (1967) and White (1980) corrections, and for clustering at the country level following Huber (1967). We also include year and industry dummies (at the one-digit SIC-code level), but we do not report their coefficients.

Across all specifications, we find that shareholder protection is negatively correlated with all-cash bids. We note that a one-point increase in the level of shareholder protection is associated with a reduction of between 13% and 18% in the probability of using only cash as the means of payment. Our interpretation of this result is that stocks are a less popular means of payment in countries with lower shareholder protection because stocks entail a higher risk of expropriation.

Among the control variables, target size is negative and significant, and cross-border, hostile bid, and tender offer are positive and significant, as we expected. Contested bids are not associated with more cash as a method of payment. The probability of using only cash as the method of payment is 17% higher in cross-border deals.

To deepen the analysis of the means of payment in cross-border deals, in Column 3 we add the difference between acquirer and target countries' shareholder protection as a further control variable. We expect that the use of stocks as a method of payment will be positively correlated with the degree of investor protection in the acquirer country, when acquirer and target countries are different. We find evidence in favor of this prediction because the coefficient on the difference between acquirer and target countries' shareholder protection is negative and significant.

Table 8
Means of payment
The table reports estimates of six Probit models for the sample of individual deals. The dependent variable is all-cash bid, or a dummy variable that equals one if the acquisition is entirely paid in cash, and zero otherwise. Independent variables at the country level are shareholder protection, a measure of the effective rights of minority shareholders, and mandatory bid rule, a dummy variable that equals one if in 1995 there was a legal requirement to make a tender offer when shareholdings after the acquisition exceed a given ownership threshold, and zero otherwise. The control variable at the cross-country level is the difference between the acquirer and target countries' shareholder protection. Control variables at the deal level are: target size, the logarithm of the target's market capitalization four weeks before the announcement; cross-border, a dummy variable that equals one if the deal is cross-border, and zero otherwise; hostile bid, a dummy variable that equals one if the deal is hostile, and zero otherwise; tender offer, a dummy variable that equals one if the deal involves a tender offer, and zero otherwise; contested bid, a dummy variable that equals one if the number of bidders is larger than one, and zero otherwise; and bidder M/B, the equity market-to-book ratio of the bidder four weeks before the announcement. In all regressions, we also include year and industry (at one-digit SIC-code level) dummies (not shown). In Column 6 we add two dummy variables that identify deals where the target firm is from the US (US targets) and from the UK (UK targets), respectively. Displayed coefficients are the change in probability for an infinitesimal change in the independent variables. The standard errors (in parentheses) are adjusted for heteroskedasticity using Huber (1967) and White (1980) corrections and for clustering at country level using the Huber (1967) correction.

Bidder M/B might be correlated with the use of stocks as means of payment because the bidder could try to take advantage of market booms, as argued by Shleifer and Vishny (2003). In Column 4, we add the bidder M/B, but we find that its coefficient is not significantly different from zero.

The mandatory bid rule might require the bidder to make a cash offer or an offer with a cash alternative, as in the UK. If so, mandatory bid rules should be positively correlated with all-cash bids. However, UK bidders often avoid the mandatory tender offer by bidding for 29.9% of the shares, which is just below the 30% threshold for the mandatory tender offer, and then acquiring the remaining shares via a share offer. In this case, mandatory bid rules should not be correlated with all-cash bids. In Column 5, we control for mandatory bid rules, and find that the coefficient is not statistically significant.

In Column 6, we show that our results are not driven by deals involving US and UK firms. The coefficient on shareholder protection is even larger in absolute terms than in Column 1, and equally significant in statistical terms when we include two dummy variables for deals in which the target is a UK or US firm, respectively.

As a further robustness check (not reported), we estimate the specification in Column 2 with weighted least squares, in which the weights are the inverse of the number of observations by country. With this procedure, all countries have the same impact on the final results. The coefficient on shareholder protection is identical to that in Column 2.

One concern is that the control variables used in regressions (5) and (6) (tender offer, hostile bid, and cross-border) are themselves endogenous. As a result, our estimates could be inconsistent. To address this issue, we estimate a recursive system with five equations, one for each endogenous variable: premium, all-cash bid, tender offer, hostile bid, and cross-border. Exogenous variables are target size, bidder M/B, shareholder protection, and mandatory bid rule. We do not present the results of these regressions here, because the coefficients on shareholder protection are similar to those in Tables 7 and 8.

4. Discussion

The results presented in Section 3 have implications for the impact of investor protection on M&A activity and the role of cross-border takeovers as a catalyst for convergence in corporate governance regimes. We discuss both implications below.

4.1. M&A activity and investor protection

Overall, the results in Section 3 characterize M&A activity as correlating with investor-friendly legal environments. We interpret these findings along the lines of La Porta et al. (2000b) and argue that a more active market for mergers and acquisitions is the outcome of a corporate governance regime with stronger investor protection.

With low shareholder protection, there are large private benefits of control (Nenova, 2003; Dyck and Zingales, 2004), and therefore the market for corporate control does not operate freely. Conversely, with high investor protection, there are low private benefits of control, and there is an active market for corporate control. Moreover, better accounting standards increase disclosure, which helps acquirers identify potential targets. Hence, there are more potential targets in countries with better shareholder protection and accounting standards. This view yields two testable predictions: across target countries, both the volume of takeovers and the takeover premium should increase with better shareholder protection and accounting standards.

The results on volume, reported in Table 3, are strongly consistent with this view. The results on the premium, reported in Table 7, are weakly consistent with this view. Table 7 shows that higher shareholder protection in the target company is associated with higher premiums, although US and UK firms drive the results. Our results reject the alternative view that the market for corporate control is a substitute for legal protection of shareholders. According to Manne (1965) and Jensen (1993), if the market for corporate control works efficiently, firms with poor corporate governance become the targets of takeovers from more efficient firms. Extending their argument across countries, the volume of M&A activity and the premium paid should be greater in countries with lower investor protection. These predictions are inconsistent with our findings.

4.2. Convergence in corporate governance

The results in Table 6 relate to the ongoing debate among legal scholars on the possibility of effective worldwide convergence in corporate governance standards. Coffee (1999) argues that differences in corporate governance will persist but with some degree of functional convergence. Hansmann and Kraakman (2001) believe that formal convergence will happen soon. Bebchuk and Roe (1999) question the idea of rapid convergence because political and economic forces will slow down any change. Gilson (2001) argues that convergence will happen through all three channels (formal, contractual, and functional).

Our findings are consistent with the prediction by Coffee (1999) that companies from countries with better protection of investors will end up buying companies from countries with weaker protection. The case for target shareholders to sell out to bidders with higher governance standards is clear. Targets stand to gain from the lower cost of capital associated with higher investor protection. However, it is not obvious why acquirers seek to take over a poorly governed company. The results in Table 7, Column 3, show that acquirers from countries with better investor protection do not pay higher takeover premiums than acquirers from countries with weaker investor protection. Hence, they share part of the surplus created by improving the corporate governance of the target.

One concern is that they might import the poorer governance of their targets (poor accounting and disclosure practices, board structures, and so on). However, anecdotal evidence of cross-border deals with high press coverage suggests that

this is not the case. The targets almost always adopt the governance standards of the acquirers, whether good or bad. In Daimler's acquisition of Chrysler, for instance, the resulting company has adopted a two-tier board structure, as required by German law. Thus, if convergence occurs, it is towards the acquirers' governance standards.

A related issue is that a deal could be motivated by the agency and hubris problems of the acquirer rather than by the desire to improve the governance regime in the target company. If so, the deal might not create value. Assessing this issue requires a study of the performance of the target and acquirer after the acquisition, which we cannot do with our large sample. Instead, we indirectly test this issue. If countries with poorer investor protection (in particular, lower governance standards, as measured by lower shareholder protection) have more severe agency problems, the hypothesis predicts more acquisitions by companies in countries with lower shareholder protection. This is not what we observe. If we sort our data by acquirer country, we find rather the opposite (not reported): more acquisitions by companies in countries with higher shareholder protection.

Our analysis also sheds light on the question as to whether cross-border deals might lead to greater international stock market integration and to a reduction of the home bias in equity investment in target countries. If the foreign bidder pays with stock, target shareholders face the problem of disposing of a new investment domiciled abroad. As a result, they might choose to keep the foreign stocks. In aggregate, these individual decisions would imply a reduction of the home bias in equity investment in target countries. We show in Table 8, Column 3, that target shareholders accept the acquirer's shares more often if the investor protection in the acquirer's country is greater than in the target's country. Hence, the reduction of the home bias puzzle goes together with a convergence in corporate governance regime. In this sense, our findings are consistent with Dahlquist et al. (2003).

5. Conclusion

Using a large sample of deals in 49 major countries, announced in the 1990s and completed by the end of 2002, we find that better investor protection is associated with more mergers and acquisitions, more attempted hostile takeovers, and fewer cross-border deals. We also find that better investor protection is associated with the greater use of stock as a method of payment, and with higher takeover premiums. These results indicate that domestic investor protection is an important determinant of the competitiveness and effectiveness of the market for mergers and acquisitions within a country.

In cross-border deals, we find that acquirers on average have higher investor protection than targets, that is, firms opt out of a weak governance regime via cross-border deals. This result indicates that the international market for corporate control helps generate convergence in corporate governance regimes across countries.

Appendix A. Description of the variables included in our study and their sources

A.1. Country-level variables

Volume	Percentage of domestic traded companies targeted in completed deals in the 1990s. Sources: SDC Platinum, provided by Thomson Financial Securities Data, and the World Development Indicators.
Hostile takeover	Attempted hostile takeovers as a percentage of domestic traded companies. Sources: SDC Platinum and the World Development Indicators.
Cross-border ratio	Number of cross-border deals as target as a percentage of all completed deals. Source: SDC Platinum.
GDP growth	Average annual real growth rate of the gross domestic product in the 1990s. Source: World Development Report.
GNP per capita	Gross national product in 1995 (in US$) divided by the population. Source: World Development Report.
Common law	Equals one if the origin of the company law is the English common law and zero otherwise. Source: La Porta et al. (1998).
Accounting standards	Index created by the Center for International Financial Analysis and Research to rate the quality of 1990 annual reports on their disclosure of accounting information. Source: La Porta et al. (1998).
Rule of law	Assessment of the law and order tradition in the country produced by the risk-rating agency International Country Risk (ICR). Average of the months of April and October of the monthly index between 1982 and 1995. It ranges between zero and ten. Source: La Porta et al. (1998).
Antidirector rights	The index is formed by adding one when (i) the country allows shareholders to mail their proxy vote to the firm, (ii) shareholders are not required to deposit their shares prior to the general shareholders' meeting, (iii) cumulative voting or proportional representation of minorities in the board of directors is allowed, (iv) an oppressed minorities mechanism is in place, (v) the minimum percentage of share capital that entitles a shareholder to call for an extraordinary shareholders' meeting is less than or equal to 10% (the sample median), or (vi) shareholders have preemptive rights that can be waived only by a shareholders' vote. Source: La Porta et al. (1998).

Shareholder protection	Measure of the effective rights of minority shareholders computed as the product of rule of law and antidirector rights divided by ten. It ranges between zero and six.
Ownership concentration	Average equity stake owned by the three largest shareholders in the ten largest nonfinancial domestic firms in 1994. Source: La Porta et al. (1998).
Cross-border regulation	Equals one if in 1995 a foreign buyer needed government approval before acquiring control of a domestic firm and zero otherwise. Source: Economist Intelligence Unit, Country Surveys.
Market return	Average annual stock market return in 1990s adjusted for inflation with the Consumer Price Index. Source: WorldScope.
Market dominance	Response to survey question: "Market dominance by a few enterprises is rare in key industries (1 = strongly disagree, 6 = strongly agree)." Source: The Global Competitiveness Report, 1996.
Mandatory bid rule	Equals one if in 1995 there was a legal requirement to make a tender offer when shareholding after the acquisition exceeds a given ownership threshold and zero otherwise. Source: Economist Intelligence Unit, Country Surveys.
Openness	Response to survey question: "Foreign investors are free to acquire control of a domestic company (1 = strongly disagree, 6 = strongly agree)." Source: The Global Competitiveness Report, 1996.

A.2. Cross-border variables

Cross-border deals$_{s,b}$	Number of deals in which the target is from country s and the acquirer is from country b, shown as a percentage of the total number of deals with target in country s. Source: SDC Platinum.
Same language	Equals one when target and acquirer's countries share the same main language and zero otherwise. Source: World Atlas 1995.
Same geographical area	Equals one when target and acquirer's countries are from the same continent and zero otherwise. We classify all countries into four areas (Africa, America, Asia, and Europe). Source: World Atlas 1995.
Bilateral trade$_{s,b}$	Value of imports by country s from country b as a percentage of total import by country s. Source: World Bank Trade and Production Database.

A.3. Deal-level variables

Premium	Bid price as a percentage of the closing price of the target four weeks before the announcement. Source: SDC Platinum.
All-cash bid	Equals one if the acquisition is entirely paid in cash and zero otherwise. Source: SDC Platinum.
Target size	Logarithm of the market capitalization of the target four weeks before the announcement of the deal in US$ million. Source: SDC Platinum.
Tender offer	Equals one if the acquisition is done through a tender offer and zero otherwise. Source: SDC Platinum.
Cross-border	Equals one if the target country differs from the acquirer country and zero otherwise. Source: SDC Platinum.
Hostile bid	Equals one if the bid is classified as unsolicited and zero otherwise. Source: SDC Platinum.
Contested bid	Equals one if the number of bidders is larger than one and zero otherwise. Source: SDC Platinum.
Bidder *M/B*	Equity market-to-book ratio of the bidder computed four weeks before the announcement. Source: Datastream.
