Fiscal Macroeconomics

Class Exercise

Consider the model to simulate debt dynamics introduced in the lectures: In practice, the dynamics of the debt to GDP ratio can be found by solving the following system:

$$sfa_t = \epsilon_t \tag{1}$$

$$R_t^{av} = rr_t + \pi_t = \mu_1 \tag{2}$$

$$g_t = \Delta y_t + \pi_t = \mu_2 \tag{3}$$

$$d_t = -f(R^{av}, g_t, b_{t-1}) (4)$$

$$b_t = \frac{1 + R_t^{av}}{1 + g_t} b_{t-1} + d_t + sfa_t$$
 (5)

Q1

- 1. in the case $\mu_1 > \mu_2$ simulte the dynamic effects of the fiscal rule $d_t = -\frac{R_t^{av} g_t}{1 + R_t^{av}} b_{t-1}$ for an initial level of debt equal to 1.4 of GDP
 - will the rule deliver debt stabilization?
 - will the rule deliver debt sustainability?
 - what is the relevance of the Stock Flow adjustment term in determining the debt dynamics?

Q2

- 1. Design and implement a fiscal rule that will allow the government to reach a target debt to GDP ratio of 60 per cent
- 2. Design and implement a fiscal rule that will allow the government to keep the level of the nominal debt at face value constant
- 3. discuss the feasibility of the empirical implementation of your proposed rule.

Q3

- 1. Extend the model to include money financing when the inflation tax shows the Laffer curve properties.
 - In the case where the real interest rate is 0.03 and real growth is 0.01, check if a constant primary surplus of 1.25 per cent of GDP deliver a sustainable debt path.
 - is it possible to achieve debt sustainability via seignorage without any intervention on the primary surplus?
