

Historical Roots of Political Extremism: The Effects of Nazi Occupation of Italy *

Nicola Fontana,[†] Tommaso Nannicini,[‡] Guido Tabellini[§]

April 2023

Abstract

We study the impact of the Italian civil war and Nazi occupation of Italy in 1943–45 on postwar political outcomes. The Communist Party, which was more active in the resistance movement, gained votes in areas where the Nazi occupation was both longer and harsher, mainly at the expense of centrist parties. This effect persists until the late 1980s. These results suggest that civil war and widespread political violence reshape political identities in favor of the political groups that emerge as winners. This benefits extremist groups and hurts moderates since the former have a comparative advantage in organizing violent conflict.

Keywords: Civil War, Political Extremism, Persistence

1 Introduction

It is well understood that the presence of large extremist parties can hinder the functioning of democratic institutions. In the most severe cases, an extremist party can directly threaten the viability of democratic rule, or opposing groups may use its presence as an excuse to abandon democracy, as in Greece in 1967 or Chile in 1973. Even in stable democracies, the presence of large extremist parties raises policy uncertainty and volatility ([Bordignon, Nannicini and Tabellini, 2016](#)), makes political compromise more difficult, can prevent alternation of office between the incumbent and the opponent, and—in a dynamic setting—can induce distorting strategic behavior by the incumbent. The origin of political extremism is less well understood, however. Throughout the 1960s and 1970s, extremist parties in Italy and France gathered over 30% and over 20% of the votes, respectively, while they were virtually absent in Austria, Germany, and the Anglo-Saxon countries. How can we explain such large differences in neighboring countries with similar economic structures and at the same level of economic development? In this paper, we argue that political extremism can emerge as a legacy of civil war and foreign occupation.

A priori, civil war and foreign occupation can impact political extremism in several ways. We investigate three theoretical hypotheses. First (H1), the increased salience of political conflict during a civil war might polarize voters on both sides. This theory is suggested by a large literature on social identity ([Bonomi, Gennaioli and Tabellini, 2021](#), [Abrams and Hogg, 1998](#)): on the one hand, conflict induces individuals to choose one side and identify with one of the opposing political groups; on the other hand, social identification leads to polarization, because individuals conform to the in-group norm, which they perceive as more extreme than it really is. Second (H2), political groups that contributed to victory might be strengthened by the war. As emphasized by [Shayo \(2020\)](#), individuals tend to identify with higher status groups; in this context, with whoever won the war. This effect is asymmetric, as it is observed only on the side that won the war, and for the groups that are perceived as contributing to victory, whether extremists or not. Nevertheless, extremist groups are more likely to benefit in practice. The reason is that they find it easier to solve the collective action problem and organize violence thanks to their radical ideology ([Walter, 2017](#)), and hence are more likely to

be perceived as having contributed to victory. Third (H3), civil wars might directly impact the party system through the supply side, as military factions evolve into political organizations (e.g., [Costalli and Ruggeri, 2015](#), [Costalli and Ruggeri, 2019](#)). The goal of this paper is to study these effects in an advanced democracy, sorting out these different mechanisms and investigating their persistence.

We study the domestic political consequences of the Italian civil war and Nazi occupation during the final two years of World War II. Between July 1943 and May 1945, Italy was a battleground between the Allied and the German forces. Italians themselves were split, with troops loyal to the fascist regime fighting alongside the Germans and resistance fighters helping the Allies. About 360,000 people died during this period, of which about 155,000 were Italians. These violent events left a strong imprint on public opinion and on the postwar political system. Political parties evolved out of the resistance movement, where postwar political leaders played an important role, and political institutions were designed to minimize the risk of a relapse into civil war or dictatorship. Our empirical strategy exploits geographic variation in the intensity of the conflict. The Allies freed Southern and much of Central Italy almost immediately, while Northern-Central Italy remained under Nazi occupation for much longer and was the turf of conflict between fascists and the resistance movement. Moreover, the Nazi troops became particularly aggressive toward partisans and civilians in the last stage of the war, and this only affected areas under German occupation.

We first show—in a series of OLS correlations—that the vote share of the Communist Party in postwar national elections is higher in municipalities where the Nazi occupation was longer and more violent. To identify a causal effect, the rest of the paper exploits the fact that—because of weather conditions and exogenous factors—the battlefield between the Germans and the Allies remained stuck for over six months near the so-called “Gothic line,” a defensive line cutting Northern-Central Italy from West to East. We apply a geographic Regression Discontinuity Design (RDD), comparing voting outcomes in municipalities just above vs below the line. The treatment is that, North of the line, the German occupation and the fighting by the resistance movement were both longer and harsher, while South of the line the Allies conducted a much less extractive occupation, free speech was allowed, and Italian political movements started claiming self-government responsibility for their country.

Our main result is that the vote share of the extreme-left parties in postwar elections is larger in

municipalities just North of the line. This effect is quantitatively important (about 9 percentage points for the Communists in the 1946 elections), and persists until the end of the “First Republic” in the late 1980s-early 1990s. The communist gain above the line is mainly at the expense of the catholic party, although this finding is less robust, suggesting that the Communists may also have gained votes from other moderate or center-left parties. Municipalities North of the line are also less likely to vote for the extreme right-wing parties linked to the fascist regime, but this effect occurs later in time and it is smaller than the vote loss of the Catholics. We find no impact on voters’ turnout.

Thus, these results are inconsistent with the hypothesis that exposure to conflict induced a symmetric increase in polarization, H1 above. To shed light on the mechanisms of the communist gain, we investigate the two other explanations summarized above, H2 and H3. According to our second hypothesis, longer exposure to civil war and foreign occupation might directly affect voters’ political attitudes. The Italian Communist Party was more active in the resistance movement than the others, and it had opposed Mussolini from the start (the Catholics instead had voted him in office). The shared emotions associated with the violent German occupation increased the salience of the conflict and could have led voters to identify with the political party that, more than others, was the symbol of the victorious resistance movement. According to our third hypothesis, instead, a longer Nazi occupation might have affected postwar political organizations. North of the line the resistance movement remained active for longer, and this may have given an advantage to the Communist Party in building grassroots organizations. These two hypotheses are not mutually exclusive.

The evidence is more consistent with the second hypothesis (H2). Indeed, the RDD analysis shows that left-wing partisan brigades were equally widespread just North and just South of the Gothic line, and their presence did not enhance the effects of the Nazi occupation on voting outcomes (i.e., the treatment effect of the longer German occupation is homogeneous in areas with and without left-wing partisan brigades). This is evidence against the mechanism that the Nazi occupation strengthened Communist Party organizations through its effect on the partisan movement. Moreover, the extreme right-wing parties, which were freer to self-organize North of the line, did not benefit from this greater freedom. A plausible interpretation of our findings is that a longer and more violent German occupation increased the salience of the civil conflict and led left-leaning voters to identify

with the Communist Party, which was more active in the war. The interpretation that war benefits the parties that are perceived as contributing to victory (whether extremists or not) is corroborated by the RDD (treatment-heterogeneity) finding that the catholic party also gained votes in the areas under a longer German occupation, but only if in those areas a catholic brigade was active (which may have reinforced the perception that catholics too contributed to victory).

To further corroborate our interpretation of the mechanism and to investigate the persistence of these effects, in November-December 2015 we conducted a random survey of about 2,500 individuals resident in 242 municipalities within 50 Km from the Gothic line. We find that memory of the civil war is stronger North of the line and among individuals who have a left-wing political orientation. There is also some weak evidence of mildly more anti-German attitudes North of the line. These findings too are suggestive that the mechanism underlying the reduced-form effects operates through the increased salience of the conflict in areas where the Nazi occupation lasted longer.

Despite its importance, the rigorous empirical literature on these issues is not very large—see also the surveys by [Walden and Zhukov \(2020\)](#) and [Davenport et al. \(2019\)](#). Our results and interpretation are consistent with the analyses of the political effects of more recent conflicts. [Daly \(2022\)](#), chapter 8, studies a large data set of civil wars between 1970 and 2015; she finds that parties who were more active in the war and on the winning side gained votes in postwar elections, irrespective of their involvement in mass atrocities.¹ [Dell and Querubin \(2018\)](#) also use geographic RDD, exploiting discontinuities in the US military strategies during the Vietnam war, and find that US bombing increased the political activities of the communist insurgency and reduced non-communist civic engagement. Thus, the mechanisms and outcomes discussed in our paper are not confined to an episode in WWII, but are part of a more general pattern.²

¹The finding that winning factions are not blamed for indiscriminate violence is not common to all studies, however. In particular, [Condra and Shapiro \(2012\)](#) use geocoded data on violence in Iraq and show that armed actors are punished for the collateral damage they inflict.

²Several other papers have studied the effects of civil wars in Africa, South Asia, and in the Middle East, generally showing that such events reinforce ethnic identities ([Besley and Reynal-Querol 2014](#), [Blattman 2009](#), [Bellows and Miguel 2009](#), [Gilligan, Pasquale and Samii 2014](#), [Bauer et al. 2016](#), [Camarena and Hagerdal 2020](#)) and tend to increase violence and radicalization ([Besley and Reynal-Querol 2014](#), [Canetti and Lindner 2015](#), [Canetti-Nisim et al. 2009](#), [Grosjean 2014](#), [Miguel, Saiegh and Satyanath 2011](#)). The effects on political participation are more mixed, with some of these papers finding that civil wars increase participation, while others find the opposite—see in particular [Gallego \(2018\)](#) and the survey by [Walden and Zhukov \(2020\)](#).

Some recent papers have applied geographic RDD to historical European data. [Cannella, Makarin and Pique Cebrecos \(2021\)](#) study the political effects of the Operational Zones temporarily annexed by Nazi Germany in the Italian North-East in 1943-45.³ They find that in these areas the Nazi occupation was more violent and, consistent with our results, the vote share of the Communist Party was persistently higher. The vote share of the extreme right was also higher in the annexed zones, although the effect is much smaller in magnitude than for the Communist Party (in these provinces, unlike near the Gothic line, a fraction of the population is German speaking and may have been less hostile to the German annexation). [Dehdari and Gehring \(2022\)](#) take advantage of quasi-exogenous division of the French regions Alsace and Lorraine after the Franco-Prussian War to provide evidence about group identity formation, showing that being exposed to occupation and repression for many decades caused a persistently stronger regional identity. Other papers have applied similar RDD methodologies but focused on migration as the main mechanism behind the political effects. In particular, [Ochsner and Roesel \(2020\)](#) study the demarcation between the Soviet and US occupation zones in Austria during 1945-1955. They show that there was a large scale Nazi migration away from the Soviet zone, which led to long lasting right-wing extremism in the US zone. [Grosfeld and Zhuravskaya \(2015\)](#) study the long term consequences of the partition of Poland between Russia, Austria-Hungary, and Prussia.⁴ Recently, [Tur-Prats and Valencia Caicedo \(2023\)](#) exploit exogenous shocks to military plans and RDD along a frontline to study the impact of the Spanish Civil war, finding that more violence is correlated with lower generalized trust and larger support for right-wing parties. Finally, [Costalli and Ruggeri \(2015\)](#) and [Costalli and Ruggeri \(2019\)](#) also study the effect of the Italian civil war on the immediate postwar election, and some of their findings are consistent with ours, although they do not look at the Nazi occupation as treatment, they only focus on the 1946 election and do not exploit any geographic RDD to make causal inference.

Our empirical findings are consistent with an important tradition in political science, which has studied key historical junctures such as external or civil wars, when new parties are born and young

³These were the current Italian Provinces of Bolzano, Gorizia, Trento, and Trieste.

⁴[Ferwerda and Miller \(2014\)](#) study the demarcation between German and Vichy zones within France. They find a more active resistance movement in the German zone. These results are challenged by [Kocher and Monteiro \(2016\)](#), who argue that they are driven by the non-random location of the demarcation zone.

generations build new political identities breaking with the past. [Mayhew \(2004\)](#) has argued that these special circumstances have lasting effects on the nature and intensity of the political conflict. On the supply side of politics, the goals and identities of political organizations can be shaped by traumatic events that give rise to new political parties. On the demand side, intense and widespread common social experiences can shape the political attitudes of citizens for years to come. For instance, writing a century after the US civil war, [Campbell et al. \(1960\)](#) argued that partisan affiliations were still largely shaped by the geographic boundaries of that conflict.⁵ Similarly, the Great Depression had a lasting influence on the image of the Republican party as the party that mishandled those dramatic events. The notion of political realignments also motivates [Balcells \(2011\)](#), who studies the political attitudes of war veterans in the Spanish civil war of 1936–38. Her results are consistent with ours, although she looks at opinion polls rather than actual behavior.

Finally, our findings that the political effects of the civil war and the violent Nazi occupation persisted for several decades, and that even today more exposed areas have a stronger memory of those dramatic events, are consistent with a large literature on the persistence of political attitudes and cultural traits. [Acharya, Blackwell and Sen \(2018\)](#) document that contemporary differences in political attitudes across counties in the US South are correlated with the local prevalence of slavery around 1860, but this correlation is not present among second generation immigrants in those same counties. [Voigtländer and Voth \(2012\)](#) find strong persistence in anti-Semitism within Germany over more than five centuries. [Fouka and Voth \(2021\)](#) find evidence suggesting that Nazi occupation had persistent cultural effects in Greece; during the recent Greek financial crisis, sales of German cars fell more in the areas where German troops committed war crimes against civilians. [Avdeenko and Siedler \(2017\)](#) study German longitudinal data and document the importance of the intergenerational transmission of political extremism from fathers to sons.⁶

The outline of the paper is as follows. The next section provides a historical summary. The data are described in section 3. In section 4 we outline our priors and empirical strategy. Sections 5 and 6 present our empirical findings, first the OLS correlations and then the RDD causal evidence,

⁵See also [Sundquist \(2011\)](#) on the long lasting legacy of the US civil war.

⁶See also [Lupu and Peisakhin \(2017\)](#), [Iwanowsky and Madestam \(2019\)](#), and [Rozenas and Zhukov \(2019\)](#) for related studies on the former Soviet Union and Cambodia.

respectively. Section 7 illustrates the results of the survey, and the last section concludes.

2 Historical Background

This section summarizes the main events that led to the birth of the post-WWII Italian political system. Since we compare the elections in the immediate postwar period to the latest free elections before the fascist dictatorship, we start with a brief account of the Italian political system before the advent of fascism. We then turn to the WWII period—discussing the nature of the foreign occupation and of the civil war (i.e., our treatment)—and finally to the postwar Italian political system.⁷

2.1 Prewar period

At the end of World War I, Italy was a constitutional monarchy and the government was supported by a parliamentary majority of liberal-moderate representatives elected in 1913. Socialist and catholic movements were emerging, however. These new parties appealed to Italian voters who had only recently been enfranchised.

Before the consolidation of Mussolini's dictatorship, three free elections were held in 1919, 1921, and 1924 under universal male suffrage. Average turnout was around 60%. In 1919 and 1921, the electoral system was proportional, but voters could cast a preference vote for candidates running in different lists (the so called “panachage” system). In 1924, the electoral system entailed a large majority premium that gave two thirds of the seats to the party gaining a relative majority in a single national district and assigned the remaining seats to the other parties according to a proportional rule. Thus, none of these electoral rules was identical to the pure proportional system with preference votes created after WWII, although all of them had important elements of proportionality.

In the 1919 election, the Italian political system was essentially split between three groups: A liberal-moderate coalition representing the political elites that had ruled Italy in the previous decades, and two emerging and antagonistic political groups, the Catholics and the Socialists. These new parties were on different positions on many issues and were unable to form viable political alliances

⁷A more detailed historical account of these periods and episodes are provided in [Romanelli \(1995\)](#), [Leoni \(2001\)](#), [Baldissara \(2000\)](#), [Collotti, Sandri and Sessi \(2000\)](#), [Collotti, Sandri and Sessi \(2006\)](#), [Gentile \(2015\)](#), [Pavone \(1991\)](#), and [Matta \(1996\)](#).

between them. In 1919 the liberal coalition retained a relative majority but, despite a large absenteeism rate, it lost many votes and seats to the Socialists and Catholics). This outcome led to a short period of instability, which resulted in a new election in 1921. The main novelties of the 1921 election were the gains obtained by the fascist candidates, who ran in the same lists as the traditional liberal bloc and the fact that the Communist Party entered the ballot for the first time.⁸ The votes and seats obtained by the Catholics and Socialists were roughly unchanged (or slightly lower) compared to 1919.

After a period of political violence and instability, in 1922 Mussolini was asked by the King to form a government. He received a vote of confidence by a parliamentary majority that included the catholic party, while the Socialists (and the small communist group) voted against him. Mussolini soon changed the electoral law to a proportional system with a large majority premium for the party with a relative majority (see above). In 1924, a new election was held, and the fascist party obtained two thirds of the votes. Although formally free and regular, this election was held in a climate of violence and intimidation. Within a few years, Mussolini further consolidated his power into a dictatorship.

Elections in 1919, 1921, and 1924 are not easily comparable between each other, but each of them displays within-municipality variation that conveys information on the underlying political preferences of the (local) population. General elections were also held in 1929 and 1934. Following a parliamentary reform enacted in 1928, these elections took the form of a referendum with only the Fascist party running and with a voting system that did not guarantee the secrecy of the vote.⁹ Moreover, to our knowledge, no data are available at the municipality level. We thus ignore these last two elections.

⁸The Italian Communist Party was founded on January 21, 1919 in Livorno as a split from the socialist movement. This was clearly a split from the extreme left as the reference model of the new party was the Bolshevik Revolution, and it was motivated by the claim “we want to do as in Russia.”

⁹Voters could vote either “Yes” or “No” to approve the list of deputies appointed by the Grand Council of Fascism. Voters were provided with two equally sized sheets, white outside, inside bearing the words “Do you approve the list of members appointed by the Grand National Council of Fascism?” The electoral sheet with the “Yes” was also accompanied by the Italian flag and a fascist symbol, while the one with the “No” had no symbol. Inside the voting booth there was a first ballot box where the voter left the discarded sheet and then delivered to the scrutineers the chosen sheet, so that they would ensure that it was “carefully sealed.” Turnout was around 90% and approval of the fascist list over 98%.

2.2 War period

2.2.1 The Gothic line

We can date the beginning of the Italian “civil war” (Pavone, 1991) in July 1943, when the Allies landed in Sicily. Since then and until May 1945, Italy was ravaged by war. On one side were the Germans, supported by the forces that remained loyal to Mussolini. On the opposite side the Allies were supported by the Italian resistance movement (operating in the areas occupied by the Germans). Throughout this period, the overall estimated casualties were about 360,000, of which about 155,000 Italians. The Italian victims of the Nazi occupation and of the civil war were 70,000–80,000. Of these, at least 10,000 were civilians killed by Nazis or fascists, and about 30,000 were resistance fighters, and about as many were fascists (see Gentile, 2015, pp. 4–5). In addition, about 40,000 civilians were deported to Germany (of which 7,500 were Jews), 90% of these died (see Rochat, 2005, p. 443).

The battlefield moved over time, but it remained stuck for several months near a defensive line prepared by the Germans in Central Italy, the so called “Gothic line.” Figure 1 illustrates the areas under German occupation, by number of days, as well as the Gothic line. Northern-Central Italy remained under German occupation for over two years, while the South for two to five months. As can be seen from Figure 1, the Germans were able to stop the Allies for several months between Rome and Naples (along the so called “Gustav Line,” which was held by the Germans between December 1943 and May 1944). From there, the battlefield moved rapidly toward Northern-Central Italy, in the area between Florence and Bologna, where the Germans had prepared a strong and continuous line of defense. Preparation for the Gothic line had begun well in advance, while the Germans were still trying to defend the area South of Rome. This allowed them to prepare an effective defense system, which stopped the Allies between the Summer of 1944 and the Spring of 1945. The Gothic line was conceived as the last defense for the German retreat. The barrier extended from the Western coast between *La Spezia* and *Massa* to the Eastern coast between *Pesaro* and *Rimini*. Basically, the line consisted of defensive positions and bunkers, hundreds of thousands of mines and booby traps, and a continuous anti-tank ditch almost six miles long; “Allied aerial reconnaissance photographs showed a dense network of machine-gun posts, gun positions and ditches.” (Holland, 2008, p. 301). It is

estimated that over 50,000 Italian forced workers were involved in building the Gothic line ([Ronchetti, 2009](#)).

Figure 1: Italy under Nazi Occupation

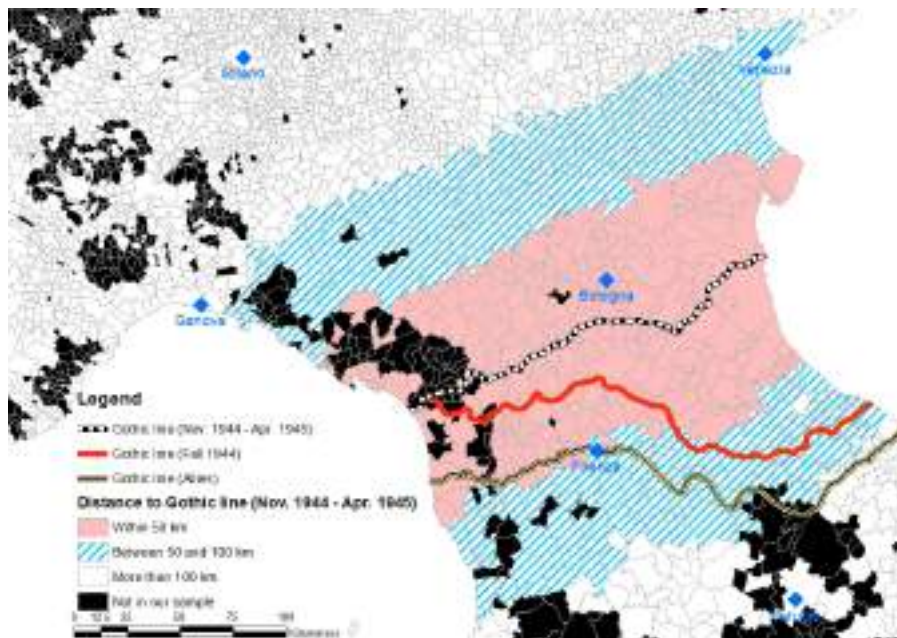

Note: Italian territory by number of days under Nazi occupation.

As can be seen from Figure 1, during the Summer of 1944 the battlefront remained stuck in an area about 50 Km South of the Gothic line. The continuous line in Figure 1 is the Gothic, which was held by the Germans between November 1944 and April 1945. The line was finally overcome by the Allies in April 1945, and in May the Germans surrendered control of Italy. The battles around the Gothic line brought much destruction to the area, with heavy casualties amongst Germans (around 48,000), Allies (32,000), and Italian fascists, partisans and civilians (altogether 30,000–40,000), see [Montemaggi \(1980\)](#). As discussed below, the Allies were extremely close to overcoming the Gothic line before the Winter of 1944, but a combination of hard weather and divergences between the US

and UK—with the former prioritizing the invasion of France and the latter paying more attention to the Mediterranean—froze the battlefront at the Gothic line for six months.

Figure 2 zooms in the area around the Gothic line, illustrating how the battlefront moved during the Summer of 1944. There are three demarcation lines. The line labeled “Allies” is where the Allies stopped between August and mid-September 1944. The line labeled “Fall 1944” is the original line set up by the Germans. Between late August and mid-September 1944, the Allies succeeded in breaching this line (so called operation “Olive”). The line labeled “Nov. 1944–Apr. 1945” is where the Germans managed to contain the US-British offensive. From the end of October onwards, the Allies and the Germans were fighting along this line. It was finally breached in April 1945. Our RDD is on the Northern-most line “Nov. 1944–Apr. 1945,” which was held for the longest period. We highlight the municipalities we include in our RDD analysis as described in Section 4 in Figure 2.

Figure 2: **Evolution of the Gothic Line**

Note: Evolution of the Gothic line over Fall 1944-Spring 1945. Observation not in our sample when missing prewar electoral outcomes.

For the sake of our empirical analysis, it is important to note that the position of the last line of defense was not only the outcome of a German decision. It was also largely due to random events, which forced the Allies to stop their offensive between late October 1944 and the Spring of 1945. In August 1944, the Allies withdrew several divisions from the Italian front to launch a new offensive

in Southern France. This decision was highly controversial: It was supported by the Americans, who wanted to create a distraction for the Germans from the ongoing battles in the rest of France, but it was opposed by the British, who instead leaned toward a stronger offensive in Italy. The American point of view prevailed, and this weakened the efforts of the Allies in Italy at a critical point in time (see [Churchill, 1959](#)). A second important random event was the weather, which deteriorated harshly in late October. These are the words used by Churchill to describe those critical moments in October 1944: “The weather was appalling. Heavy rains had swollen the numberless rivers and irrigation channels [...]. Off the roads movement was often impossible. It was with the greatest difficulty that the troops toiled forward. [...] Not until the spring were the armies rewarded with the victory they had so well earned, and so nearly won, in the autumn” (see [Churchill, 1959](#), p.839).

2.2.2 Foreign occupation and resistance movement

In the North, Mussolini tried to revamp the fascist regime by claiming statehood for the areas under German occupation (with the exclusion of two territories directly annexed to the German Reich, close to the Alps and to the Northern Adriatic coastland) and by setting the new capital of his *Repubblica Sociale Italiana* (RSI) in the small town of *Salò*. But this experiment resulted in little more than a Nazi-backed puppet state, dependent entirely upon Germany and with no autonomous domestic or foreign policy of any sort. The Nazi occupation of Northern Italy is unanimously deemed as violent and extractive by the historical literature. As Rudolf Rahn, the German diplomat who was the plenipotentiary to the RSI, put it: “Everything in occupied Italy must be exploited by us for our war effort” (see [Holland, 2008](#), p. 111). This meant coerced labor and deportations, handing over of all gold reserves, shutting down of factories to ship equipment to Germany, full control of the remaining factories for military purposes, and food reserves (if any) packed off to Germany.

In Allied-held Italy, all areas close to the battlefield were directly run by the Allied Military Government (AMG) and then, as the front advanced up toward the North, they were passed back to the authority of the Italian government, formally appointed by the King. At first, under Prime Minister Pietro Badoglio, the political legitimacy of the government was weak, since the monarchy was implicated with the fascist regime. But then the political parties outlawed by the fascist regime and active

in the resistance movement (see below) gradually took responsibility and joined the governments lead by Ivanoe Bonomi from June 1944 until the end of WWII.

Although the autonomy of the government was severely limited by the Allied Control Commission, self-determination was much stronger South of the line and, most importantly, free speech was moving Italy closer to democracy. In particular, the Bonomi government started having greater responsibility after September 1944, when Churchill and Roosevelt made a joint declaration shaping the future path toward Italy's self-determination and economic recovery. The sharp divide between the political (and psychological) situation North vs South of the Gothic line is best described by Italian lieutenant Eugenio Corti (see [Holland, 2008](#), p. 251, italics ours): "I wondered if the British and Americans realized that *behind their lines* one could feel a respect for men. It felt like this whenever one saw notices where occupation troops threatened fines and at most jail sentences that *on the other side* were invariably punished with death. We would no longer hear talk of executions, and this fear—which makes man nothing more than a beast—would no longer hang over us."

Throughout the civil war period, the resistance movement grew rapidly, from a few thousand fighters in the Fall of 1943 to several tens of thousands one year later. In addition, it is estimated that around 20,000 civilians were directly connected to the resistance movement, even if only a few of them nested into political coordination (see [Bocca, 2012](#), p. 265). Although the movement was spontaneous and did not have strong party affiliations, the leaders of the various groups were active members of political parties that the fascist regime had disbanded. Three main political affiliations can be identified: The left-wing groups, linked with the Communist and Socialist Parties; the catholic groups, linked with the Christian Democratic Party; and other centrist groups, linked with liberals that had opposed Mussolini. In addition, there were several other small groups with no explicit political affiliation.¹⁰ The left-wing brigades, and to a smaller extent the catholic, were by far the largest and most active organizations. The political parties active in the resistance movement joined forces in the "National Liberation Committee," which gave crucial support to the Bonomi governments.

In the North, the civil-war nature of the conflict was reinforced by the decision of Mussolini to

¹⁰In our data set referring to the area around the Gothic line, we count 115 communist brigades (*Garibaldi*), 44 other left-wing brigades (*Matteotti* and *Giustizia e Libertà*), and 59 non-marxist brigades (*Fiamme Verdi* and others).

give birth to the “black brigades,” paramilitary groups directly run by the Fascist Party, which also attracted tens of thousands of volunteers, although poorly trained and equipped.

According to historical accounts, the effects of German occupation and of the civil war on the civilian population were not evenly distributed in time and space. As stressed by [Cavaglioni \(2015, p.96\)](#), the civil war was almost absent in most regions of the South as they were rapidly freed by the Allies, it was long and harsh in Piedmont, and it varied in Emilia-Romagna based on the duration of the Nazi occupation. [Gentile \(2015\)](#) stresses two stylized facts about the German occupation. First, combat troops near the front line were more ruthless and prone to hurt civilians than other troops in charge of logistics and administration. This reflected both the selection and composition of such troops, as well as the additional stress and danger that they faced. Second, following hierarchical orders, the German attitudes and tactics changed over time, and became particularly aggressive toward partisans and civilians alike from the Summer of 1944 onwards, when the danger posed by the resistance movement became more apparent. On June 17, 1944 Field Marshal Albert Kesselring, the German commander in chief in the Mediterranean, issued an order promising indemnity to soldiers who should exceed “normal restraint” in the choice of repression methods.¹¹

Our (local) source of exogenous variation—the Gothic line—captures a treatment made up of both (i) the extractive Nazi occupation that characterized the last period of WWII and (ii) the civil war between the fascist and partisan brigades. The compound nature of this treatment reinforces its occurrence, as both elements operate along the same spectrum of political alignment. The control group includes municipalities occupied by the Allies, where free speech was allowed and self-determination by Italian authorities gradually developed.

2.3 Postwar period

The resistance movement and the political parties to which it was linked played a key role in the immediate aftermath of the war. Several leaders of the movement became prominent political figures and were elected in the postwar Parliament for several legislatures. The civil war contributed to

¹¹Nazi authorities also tried to make this clear to the Italian population. In the Summer of 1944, German planes dropped leaflets over Central Italy with the warning: “Whoever knows the place where a band of rebels is in hiding and does not immediately inform the German Army, will be shot. Whoever gives food or shelter to a band or to individual rebels, will be shot. Every house in which rebels are found or have stayed, will be blown up” (see [Holland, 2008, p. 145](#)).

shaping the political identity of these parties and gave them visibility and popularity that they had not enjoyed before, also due to the repression imposed by the fascist regime.

The first key decision of the new political leadership was to hold an election for a constitutional assembly. The election was held in 1946, simultaneously with a referendum on whether to abandon the monarchy. Monarchy lost and Italy became a Republic. With this election, suffrage became universal, thus women had the right to vote for the first time. The electoral rule for the constitutional assembly and for all subsequent elections until 1992 was proportional. All the main parties presented lists of candidates at the constitutional assembly, and the party system did not change significantly afterward. Hence, the election for the constitutional assembly is comparable to subsequent political elections. The first regular election was held in 1948. The only difference in party labels is that in 1948 the Communist and Socialist Parties ran together under the label of “Popular Front,” whereas they had run separately in 1946 constitutional election. In 1953 and in subsequent elections they split again. Monarchist parties progressively disappeared from the political scene; the last election in which they ran was in 1968. On the extreme right, a party close to the fascists, *Movimento Sociale Italiano* (MSI), was founded on December 26, 1946 and appeared on the ballot in the 1948 election, but consolidated its vote share (around 5–7%) only from the 1953 election onwards.

The political system that emerged in the late 1940s reflected the legacy of the civil war in several respects. First, as already noted, most political leaders had played an important role in the resistance movement, at least in the period 1943–45. Second, the party system was highly polarized. On the left the Communists were the largest party (the biggest Communist Party in Western countries), which at the time had strong ideological and financial links with the Soviet Union, while the extreme right remained loyal to the fascist regime.¹² The Italian Communist Party always maintained strong links with the Soviet regime; for instance, it supported the Soviet invasion of Hungary in 1956, most of its leaders received training in Moscow, and financial aid from the Soviet Union reached the Italian Communists as late as in the early 1980s (Cervetti, 1999). Also on economic policy, the Communist Party maintained an extremist stance until the early 1980s, for instance, opposing the Bill of Workers’

¹²Until the early 1990s, the two biggest parties were the Christian Democrats, the ruling party over all of this period, with average vote shares of 35–40%, and the Communist Party, whose vote share grew from 15–20% right after the war to more than 30% in 1976. The vote share of the Socialist Party oscillated around 10–15%.

Rights in 1970 (as it would have tempered and delayed the fall of capitalism) and the entry of Italy in the European monetary system in 1979. Third, and partly as a result of such ideological polarization, one of the main goals of the Constitutional assembly was to create a very inclusive and consensual political system, to minimize the risk of violent conflict. This resulted in a strictly proportional system, perfect bicameralism, and several checks and balances that diluted executive powers.

The main features of the Italian postwar political system remained roughly unchanged until the early 1990s, when several things changed. First, with the collapse of the Soviet Union, the Italian Communist Party made a credible and pronounced shift toward social democracy. Second, the Christian Democrats and the Socialist Party collapsed under the weight of corruption scandals, leaving room for new moderate forces led by Silvio Berlusconi. Third, the electoral rule was changed to a mixed-member system. Our analysis ends just on the edge of this transition.

3 Data

This section describes our variables. Appendix A provides more detail on the data. The unit of observation is the municipality.

3.1 Political outcomes

We measure political outcomes by the percentage of votes received by political parties at the 1946 election for the constitutional assembly, and in all subsequent 10 national elections for the Chamber of Deputies until 1987 included.

We consider three political groups. First, the radical left, measured by the votes given to the Communist Party. We call this variable *Communist*. Since in 1948 the Communists and the Socialists formed a single electoral list, we also consider the votes received by these two parties together, and we call it *Communist and Socialist*. The second group is the Christian Democratic Party, which we call *Catholic*. The third group, which we call *Right-Wing*, consists of the post-fascist party (MSI) and smaller parties that supported the monarchy. The source of the electoral data is the Italian Ministry of Interior.¹³

¹³From the same source, to evaluate the persistence hypothesis, we also collected the percentage of votes received by new political parties in the 7 national elections from 1992 to 2013 for the Chamber of Deputies. After the political corrup-

We also collected data on the last free elections held before the advent of fascism, namely in 1919, 1921, and 1924. The Communist Party was very small in the 1921 and 1924 elections (and did not exist in 1919), so we lump together the socialist and communist votes in the pre-fascist period to gain precision. The right-wing vote cannot be separately measured in 1921, since fascists were running together with the more traditional and moderate liberals in that election. Hence, for the pre-fascist, period we mainly use the *Catholic* and *Communist and Socialist* vote shares.

Since there are several missing observations in prewar data, in our baseline analysis we fill the missing observations in each election exploiting the remaining two elections plus additional observables. Our baseline sample consists of about 5,700 municipalities for which we have both postwar and prewar political outcomes. As shown below, the results are robust to only using available prewar data, with no imputation for missing observations.

Thanks to [Acemoglu et al. \(2022\)](#) we have also information on fascist presence at municipality level. They construct fascist vote share in 1921 and in 1924 elections combining [Corbetta and Piretti \(2009\)](#), 1,200 local and national historical newspapers and local state archives.¹⁴ Moreover they construct a measure of violence (number of violent episodes per 1,000 inhabitants for the period 1920-1922) from [Franzinelli \(2003\)](#). Finally, they collected information on local branches of the Fascist Party in September 1921 from the prefect reports located in state archives throughout Italy from which a dummy for the presence of a Fascist branch is constructed.

Since no elections were held after 1924, we collected two variables that measure opposition to the regime in the municipality during the fascist period. Our first variable is the fraction of citizens under political surveillance (source: Casellario Politico Centrale).¹⁵ The original source reports the political affiliation, the municipality of residence and the year in which the citizen became under surveillance. We construct the share of Left-wing citizens under surveillance as the sum of communist, socialist, or anti-fascism citizens under surveillance between 1925 and 1942 over the 1921 population (x1000). As

tion scandal “Mani Pulite,” the Italian party system was completely changed. We consider five political groups: Extreme Left, Center-Left, Center, Center-Right, and Right. From 1996 onwards, the two major coalitions were represented by the Center-Left and Center-Right.

¹⁴As mentioned, in 1921, the moderate right and fascist parties were running together, [Acemoglu et al. \(2022\)](#)’s 1921 fascist vote shares and our *catholic* 1921 vote shares would marginally differ, depending on which parties are included

¹⁵We thank Francesco Barilari for helping collect these data.

shown in Table 1, this variable correlates positively with communist and socialist prewar vote shares while it is uncorrelated with the prewar catholic vote.

Second, from ANPI (National Association of Italian Partisans) we collected a list of 3,117 partisans with a short biography. This database is only a sample of all partisans, but it was built to represent the political diversity of the resistance movement and includes almost all of the national and local leaders of the movement. From this source, we create two dummy variables, for whether at least a partisan in our sample was born in the municipality, and for whether he/she was linked to a left-wing party in the postwar period. These variables thus capture the strength of local opposition to the fascist regime, rather than the presence of brigades in the area even if it is positively correlated with it. As shown in Table 1, also this measure of local opposition to fascism correlates positively with communist and socialist prewar vote shares while it does not correlate with the catholic vote.

3.2 War-related variables

To explore the mechanisms that could affect political outcomes, we collected several variables related to the Nazi occupation and the civil war. First, using Baldissara (2000), we coded the presence of partisan brigades in the municipal area. We distinguish between left-wing brigades and other partisan brigades, but the results are robust to a finer disaggregation between different partisan groups.

Second, we code episodes of violence by the fascists or by the Germans. We define a dummy variable for municipalities with at least one episode of violence, and distinguish between episodes where the majority of victims were civilians or partisans. The source is the “Atlas of Nazi and fascist massacres” (ANPI-INSMLI 2016).

Third, we code the location of two German divisions that were particularly violent and committed several crimes against civilians: the 16th SS-Panzer-Grenadier-Division “Reichsfuhrer-SS” and the “Hermann Goering” division (Gentile 2015). Their exceptional violence can be seen in Appendix Figure C.1 in Appendix C. Based on the German archives consulted by Gentile (2015), we have records on the precise location of these troops throughout the Italian civil war. We construct a dummy variable that equals 1 for municipalities within 15 Km from the location of either one of these divisions.

Table 1: **Citizens under surveillance 1925-1942**

	Dependent variable:					
	Left-wing citizens under surveillance 1925-1942			Birthplace of a partisan		
	(1)	(2)	(3)	(4)	(5)	(6)

Observations	5490	5490	5490	5698	5698	5698
R-squared	0.189	0.202	0.166	0.128	0.146	0.116
Controls	No	Yes	Yes	No	Yes	Yes
Fixed Effect	Province	Province	Region	Province	Province	Region

Note: Robust standard errors are displayed in parentheses in each second row; standard errors corrected for spatial correlation are displayed in parentheses in each third row. Significance level: ***<0.01, **<0.05, *<0.1. *Left-wing citizens under surveillance*: Number of left-wing (communist, socialist and anti-fascist) citizens under surveillance over 1921 population (x1000). Parties in the pre-fascist period have been lumped using as reference [Leoni \(2001\)](#), in this table only the vote shares has not been multiplied by 100. See Appendix A for more details on these aggregations. Other regressors include: Share of illiterate 1921, population density 1921, latitude, longitude, maximum altitude in the municipality, elevation city hall, and Province or Region Fixed Effects.

Fourth, we collected data on deportations to Germany. During WWII, about 40,000 Italians were deported to Germany (about 7,500 were Jewish). Thanks to [Mantelli and Tranfaglia \(2013\)](#), we have data on the number of political deportations by the municipality of capture (about 6,500 individuals).

Finally, we code the duration of the German occupation in each province, from the detailed maps in [Baldissara \(2000\)](#). We were able to reconstruct the duration of the German occupation at the municipal level only near the Gothic and the Gustav lines, where the battlefront was more clearly defined. Throughout the rest of Italy, data on the duration of the German occupation are at the province level only.¹⁶

¹⁶Appendix Table C.1 reports the correlation matrix of the main variables of interest in the entire sample of the OLS regressions, showing that these variables are only weakly correlated.

3.3 Other city characteristics

From the Census (ISTAT) we collected data on total resident population, population density, and literacy rates for the years 1911, 1921, and then 1951, 1961, 1971, 1981, and 1991. As an indicator of economic development, from the 1951 Census, we collected data on the number of industrial plants per capita in each municipality. We also collected data on the elevation at the city hall, and on maximum and minimum elevation in the municipality. Finally, to include appropriate fixed effects, we reconstructed provincial borders at different dates. As a default, we use provinces and regions as defined in 1921, but results are robust to use administrative boundaries defined on the basis of the boundaries at later dates. Thanks to [Fontana et al. \(2021\)](#) we also got data on the number of industrial plants and workers in 1927 (*Censimento Industriale 1927*), the number of agricultural firms and workers, the number of livestock, and surface devoted to agricultural production in 1929 (*Catasto Agrario 1929*). Appendix Table [C.2](#) reports summary statistics of these variables in the entire sample; Appendix Table [C.3](#) provides the same summary statistics for municipalities within a 50 Km radius around the Gothic line.

4 Empirical Strategy

4.1 Prior hypotheses

Did the German occupation and the civil conflict leave a mark on the postwar Italian political system? In particular, did it affect the support enjoyed by extremist political parties? A priori, there are three main reasons to expect a lasting impact, the first two operating directly on citizens' attitudes, and the third one operating on political organizations.

First hypothesis (H1). In the areas under German occupation, the civil war between the fascists and their opponents was both longer and harsher. As suggested by the literature on social identity ([Bonomi, Gennaioli and Tabellini, 2021](#), [Abrams and Hogg, 1998](#)), this in turn could lead to more entrenched and radicalized positions on both sides, reinforcing opposite political identities and shaping attitudes in favor of both the Communists and the extreme Right-wing Parties at the expense of the moderate parties. Therefore, the legacy of political violence should be political polarization.

Second hypothesis (H2). The German occupation was actively opposed by the Italian resistance movement. To suppress it, Nazis often resorted to extreme forms of violence, not only against resistance fighters but also against civilians. Moreover, the extractive nature of the Nazi occupation, especially when contrasted with the Allies' behavior, could affect political attitudes directly. Victory against the foreign oppressor and liberation from the fascist regime could lead Italian voters to identify with the parties that contributed to these outcomes and enjoyed higher status for this reason (Shayo, 2020). This would favor the Communists, who were more involved in the resistance movement and stood up more forcefully against the Nazis. Indeed, the Italian Communist Party capitalized on this channel in the aftermath of WWII, by pitching itself as the true guardian of the legacy of the resistance movement. This effect is likely to be larger in the areas of more intense fighting and of harsher violence, where the memory of the war was accordingly stronger.¹⁷

Third hypothesis (H3). The German occupation could affect political organizations. Right-wing parties loyal to Mussolini were freer to self-organize in the areas under German occupation. But the presence of active partisan brigades could also matter, since the postwar party system grew out of the resistance movement, and partisan brigades could be exploited to build grassroots organizations, as stressed by Costalli and Ruggeri (2015). Through this channel, a longer German occupation could thus give an advantage to the Communist Party (since its partisan brigades were more active and better organized), as well as the right-wing parties linked to fascism.

4.2 Identification

Our estimation strategy exploits geographic heterogeneity in the duration and nature of the Nazi occupation. We start by looking at the OLS correlations in all of Italy:

$$Y_i = \alpha_0 DUR_i + \alpha_1 V_i + \alpha_2 PB_i + x_i' \beta + \gamma_r + \varepsilon_i, \quad (1)$$

¹⁷Note two possible caveats to this argument, that we consider in our empirical analysis. First, despite a much less prominent role, the catholic movement too participated in the resistance movement. Therefore, we could expect the catholic party to also gain votes where it was perceived to be belligerent against the German occupation. Second, some of the Nazi violence was in retaliation for partisan attacks, and the local population may have blamed the partisan movement for this. If so, we could expect a negative correlation between Nazi violence against civilians and the Communist vote in the areas where the left-wing brigades were active.

where Y_i is the vote share of the Communist Party in municipality i in the 1946 elections (or in later elections); DUR_i is the duration of the Nazi occupation (measured in years); V_i measures the occurrence of violence; PB_i measures the presence of partisan brigades in the area of the municipality; x_i is a vector of covariates including our measures of opposition to the fascist regime, electoral outcomes in 1919, 1921, and 1924, illiterate share and population density in 1921 and 1951, altitude, longitude, latitude, and a constant; γ_r are region or province fixed effects (as defined in 1921); ε_i is the random error term, capturing all omitted factors. The parameter α_0 captures the association between the treatment of interest and electoral outcomes. The parameters α_1 and α_2 shed light on possible mechanisms, operating on the supply or demand side respectively.

Despite the inclusion of all these covariates and province or region fixed effects, some of the omitted factors in ε_i might be correlated with both the treatment and political outcomes. This is why, to identify the causal effect of the Nazi occupation, we implement a geographic RDD and compare post-war political outcomes in municipalities just above vs below the Gothic line. As argued in Section 2.2.1, this defensive line can be seen both as continuous and as good as random. To avoid the risk of confounding the effect of the Gothic line with that of pre-existing administrative boundaries, we always control for region fixed effects - as shown in the appendix, results are similar when controlling for province fixed effects (as defined in 1921).¹⁸ This implies that we draw inferences by comparing municipalities within the same region or province that are North vs South of the line. Our identifying assumption is that, after controlling for distance from the line (and for other covariates), being just North or just South of the Gothic line is a random event uncorrelated with other unobservable determinants of political outcomes. This assumption can be indirectly tested and cannot be rejected for several pre-treatment observables. Any difference in political outcomes between municipalities North vs South of the Gothic Line can thus be attributed to the difference in the duration of the Nazi occupation. The treatment for being North of the line is a longer exposure to the Nazi occupation and a more intense civil war for about six more months.

¹⁸In the 100 km neighborhood of the Gothic line there are 742 municipalities (in our sample), belonging to 5 regions and 25 provinces. Several of these provinces lie entirely North or South of the Gothic line, however. The Gothic line cuts through four provinces (Bologna, Firenze, Lucca and Ravenna) that belong to two different regions (Tuscany and Emilia-Romagna).

Formally, let d_i be the distance (in Km) from the Gothic line, with negative (positive) values identifying towns South (North) of the line, We estimate the following model in the interval $d_i \in [-\Delta, +\Delta]$:

$$Y_i^{post} = \sum_{k=0}^p (\delta_k d_i^k) + T_i \sum_{k=0}^p (\alpha_k d_i^k) + x_i' \beta + \eta_i, \quad (2)$$

where Y_i^{post} is any post-treatment outcome; T_i is a dummy identifying whether municipality i is North or South of the Gothic line; x_i is a vector of (time-invariant and pre-treatment) covariates that include prewar vote shares and region or province fixed effects; p captures the order of the (spline) polynomial control function; η_i is the error term. The bandwidth Δ is either a discretionary threshold (50 or 100 km) or an optimal bandwidth as in [Calonico et al. \(2017\)](#). The parameter α_0 identifies the treatment effect of interest.¹⁹ As suggested in [Cattaneo and Titiunik \(2022\)](#), we report MSE optimal conventional point estimates while inference considers robust-bias adjusted procedures. We report robust-bias adjusted 95% confidence intervals and p-values in Tables, while Figures report robust-bias adjusted 95% confidence intervals (note that confidence intervals are not necessarily symmetric around the point estimates). To avoid comparing municipalities close to the line but located far from each other along the East-West dimension, we perform robustness checks by including latitude and longitude or fixed effects for 25 Km intervals of the Gothic line in the vector x_i ([Dell 2010](#)).

RDD allows us to estimate the causal effect of the Nazi occupation on postwar elections but does not uniquely identify a particular mechanism. To discriminate between alternative hypotheses, we need additional (and stricter) assumptions. First, note that if we replace the outcome variable in equation (2) with a set of pre-treatment variables Y_i^{pre} , we can run balance tests that should normally deliver zero effects for the RDD to be valid. If we instead replace the outcome variable with “contextual” factors that happen to be potentially present in the context of Nazi occupation, we can test for different potential mechanisms. Assume, for example, that we find a significant discontinuity in con-

¹⁹The estimated coefficient $\hat{\alpha}_0$ from equation (2) is not directly comparable with $\hat{\alpha}_0$ from equation (1), because they are measured in different metrics and because the former is a local effect. Indeed, α_0 in (2) is the causal effect of six more months of Nazi occupation in a period associated with intense violence (experienced or threatened). For the sake of comparison between the OLS and RDD coefficients, one should keep in mind that, if we use DUR_i as the outcome variable of the RDD estimations defined in equation (2), we find point estimates in the range between 0.463 and 0.563 (depending on the estimation method; all statistically different from zero at the 1% significance level), corresponding to half a year as expected.

textual factors that are likely to affect voters' attitudes, but not party organizations. To interpret this as evidence supporting H2, we also need to assume that there are no unobserved variables that impact voters' attitudes and have a discontinuity at the Gothic line. The same holds for contextual factors that are likely to affect party organizations, but not voters' attitudes. The variables V_i (occurrence of violence) and PB_i (presence of brigades) are interesting contextual factors, as the former is likely to impact collective memory and the latter to shape local organizations in the postwar period.

Given the number of hypotheses tested, as suggested in [Eggers et al. \(2015\)](#) and [de la Cuesta and Imai \(2016\)](#), we verify whether some rejections of the null hypothesis should be considered as false rejections. In Appendix [B.1](#) we consider [Westfall and Young \(1993\)](#) technique.

In principle, similar estimates could be done around the Gustav line, where the Germans also stood for several months. A number of reasons discouraged us from doing so, however. First, the battle for the Gustav line occurred much earlier in time, when the resistance movement was not yet organized (within 50 km there are only 24 municipalities with at least one partisan brigade, all North of the Gustav line). The civil war did not reach those areas, and the civilian population did not suffer as much damage and casualties as in Central Italy. This also reflected German orders, which became much more intolerant and aggressive against civilians only at a later stage (see [Gentile, 2015](#)). Furthermore, prewar voting outcomes are missing for a large number of municipalities around the Gustav line (56% of the municipalities within 50 km).

5 OLS Estimates

In this section, we estimate equation (1) by OLS. In [Table 2](#), the dependent variable is the Communist Party vote share in 1946. We report both robust standard errors (second row) and standard errors corrected for spatial correlation (third row) as in [Conley \(2008\)](#), following [Hsiang \(2010\)](#). All columns include province fixed effects. We first introduce, one by one, the proxies for DUR_i , V_i and PB_i from equation (1). In column (1) the Communist vote share is positively associated with the duration of Nazi occupation (in years). In column (2) it is positively associated with the occurrence of violence during the war (measured both by having at least one episode of violence and being within 15 Km from violent Nazi divisions). In column (3) we consider two indicators for the presence of partisan

brigades (left-wing or any other brigade). The presence of partisan brigades is negatively correlated with the Communist vote share, but this result is not very robust to the inclusion of control variables in subsequent columns. Finally, in column (4) we include all the previous variables and the estimated coefficients remain quite stable.

These results remain stable when we control for a wide range of demographic and geographic characteristics of the municipalities (column 5). In column (6) we also control for the outcomes of prewar elections; some coefficients drop in magnitude, and interestingly the estimated coefficient on the presence of partisan brigades is no longer statistically significant. Finally, in column (7) we include our proxies for local opposition to the fascist regime, namely the dummy variables for the birthplace of a partisan (any partisan and a left-wing partisan) and the share of citizens under surveillance for political reasons (either because left-wing or any other political affiliation). All these variables, except the last one, are highly positively correlated with the postwar communist vote share, but the estimated coefficients on the variables of interest (the duration of the Nazi occupation, the indicators of violence and for the presence of partisan brigades) are similar and remain statistically significant with robust confidence intervals.

According to column (7), half a year of additional Nazi occupation is associated with an increase in the Communist vote share of about 1.7 percentage points (i.e., about 11.3% of the average vote share in the whole sample of 5,559 municipalities with no missing values). The occurrence of at least one episode of violence is associated with an increase in the communist vote share of 0.7 percentage points (i.e., about 4.4%). Being close to the two violent Nazi divisions is associated with an increase in the communist vote share of 1.6 percentage points (i.e., about 10.9%).

The association between the communist votes and the presence of left-wing partisan brigades is not statistically different from zero, while the presence of other brigades is negatively associated with the communist votes.

Results in Appendix Table C.4, column (2), show that the correlation between the communist vote and days of occupation is non-linear. As the duration of the occupation increases, the positive relationship with the postwar electoral results is stronger. A municipality with 700 (or more) days of occupation has, on average, 11.2% higher vote share for the Communists in 1946 than one with

Table 2: OLS Estimates – Baseline

	Dependent variable: Communist 1946						
	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Note: Robust standard errors are displayed in parentheses in each second row; standard errors corrected for spatial correlation are displayed in parentheses in each third row. Significance level: ***<0.01, **<0.05, *<0.1. *Communist 1946*: Vote share of the Italian Communist Party (PCI) in the 1946 election. *Years of occupation*: years of occupation measured at province level (see Appendix for exceptions). *At least one violence episode*: Dummy equal to 1 if records report at least one episode of violence in the period considered. *Within 15 Km of violent Nazi divisions*: Dummy equal to 1 if the minimum distance of the municipality from one occupied by either RFSS or HG Division is less than 15 Km (using city hall as reference point). *Presence of partisan brigades*: Dummy equal to 1 if the area of the municipality intersects the area of operation of the partisan brigade (left-wing or other). *Birthplace of a partisan*: Dummy equal to 1 if a partisan (or a left-wing partisan) is born in the municipality. *Citizens under surveillance*: Number of citizens (left-wing or other political affiliations) under surveillance over 1921 population (x1000). Other regressors include: Share of illiterate 1921 and 1951, population density 1921 and 1951, latitude, longitude, maximum altitude in the municipality, elevation city hall, vote shares of Communist-Socialist and Catholic in 1919, 1921, and 1924 and Province or Region Fixed Effects.

roughly 150 days. Moreover, all results are qualitatively similar or stronger if we restrict the sample to regions where the occupation lasted more than one year for at least one municipality (column 3).

Overall, these correlations are suggestive that demand, rather than supply side factors, might explain the support for communism in the aftermath of the civil war. The Communist Party gained votes in municipalities where the Nazi occupation lasted longer and was more violent, and where citizens

were more willing to embrace the cause of radical opposition to the fascist regime, as captured by the dummy variable for being the birthplace of a partisan or a left-wing partisan and by the share of left-wing citizens under surveillance. On the other hand, the actual presence of partisan brigades connected with the Communist Party is not robustly correlated with the communist vote share, as the estimated coefficient is no longer significant (and also falls close to zero in size) as soon as we introduce the 1919-1924 electoral results as additional control variables.

These estimates cannot be taken as entirely causal, however. Some (though not all) of the German violence was concentrated in areas where partisan troops or local hostility were stronger, so there could be some omitted variables. Although [Holland \(2008\)](#) and [Gentile \(2015\)](#) stress that the location of élite troops was generally driven by military or logistical concerns (the war against the Allies, or the need to rest and train new conscripts), we cannot rule out that they were sent to areas with stauncher Italian opposition. Moreover, in the more demanding specifications of columns (6) and (7), most or all variables of interest lose significance when standard errors are corrected for spatial correlation. This is not too surprising, given that we also control for province fixed effects besides many other regressors, but it indicates that these correlations are not precisely estimated.²⁰ That's why we now turn to a causal test of these findings through geographic RDD.

6 RDD Causal Effects

This section compares outcomes in municipalities just above and just below the Gothic line. Throughout we report five sets of RDD estimates. In the first four regressions, the control function in the running variable (distance from the line) is expressed as a first and second-degree spline polynomial, and the sample is restricted to municipalities within 50 Km and 100 Km from the line.²¹ Following [Gelman and Imbens \(2019\)](#), we do not report polynomial specifications of higher degrees. The fifth specification is a local linear regression with optimal bandwidth, estimated as in [Calonico et al. \(2017\)](#). As noted above, throughout we include region fixed effects and prewar vote shares, but results

²⁰We have also estimated a more conservative specification with all variables aggregated at the province level (there are 70 provinces in our sample). The estimates and patterns of significance are not very different from those reported here with spatially adjusted standard errors and are available upon request.

²¹Results in the main text will always present all the specifications while results in Appendix will present only results within 50 km and local RDD. All the results are robust to also looking at 100 km and available upon request.

are very similar or stronger without these conditioning variables or considering a different set of fixed effects (province fixed effects or a 25 km grid).

6.1 Balance tests

We start by reporting balance tests for pre-treatment observables (Y_i^{pre}). Results are shown in Appendix Table C.5. Only one coefficient is statistically different from zero (population density in 1921, in only one specification and at the 10% significance level); therefore, no consistent pattern emerges. Note that almost all of these variables have highly significant estimated coefficients in the OLS regressions in Table 2 above, suggesting that they are relevant correlates of political outcomes.

Appendix Table C.6 considers prewar vote shares (Panel A), fascist presence variables (Panel B), and proxies of opposition to fascism after the last free elections and before the civil war (Panel C). Communist and socialist vote shares seem to be higher above the line, but very few estimated coefficients are statistically significant. The most worrying coefficient may be the local RDD for Socialist 1919: however, the algorithm for optimal bandwidth selects a very wide interval (roughly 113 km), making comparisons with smaller bandwidths difficult.²² Fascist presence looks balanced above and below the Gothic line. The few estimates statistically significant are sensitive to the specification and cutoffs considered both in terms of magnitude and sign. Given the large number of tests run, we could have some false rejections of the null that all prewar variables are balanced.

This conclusion is also suggested by the placebo tests discussed below, where no systematic unbalance in prewar vote shares is visible. In any case, in what follows when reporting RDD results on the postwar vote shares we always condition on prewar vote shares.

The estimates in Panel C are also reassuring on the balance of attitudes during the fascist period. Here the outcome variables are our proxies of opposition to the regime, namely the shares of citizens under surveillance for political reasons and the dummy variables for the birthplace of partisans. We can never reject that these two variables are balanced around the Gothic line. Note that partisans were disproportionately recruited from the left, and their birthplace is strongly correlated with the postwar

²²Indeed, the stark difference in the point estimates of Socialist 1919 with the first-order or with the second-order polynomial already shows the sensitivity of the RDD results for this variable as we move away from the threshold, cautioning against giving too much emphasis to estimates in large geographic intervals.

communist vote share (see Table 2 above) and with prewar vote shares (Table 1). Likewise, the share of citizens under surveillance correlates positively with communist and socialist vote shares both in the postwar period (as shown in Table 2 above) and in the prewar period (as shown in Table 1).²³

6.2 Election outcomes and persistence

We start by illustrating graphically the difference between communist vs catholic votes in 1946 around the Gothic line. In Appendix Figure C.2 we plot the difference between the communist and catholic vote shares in 1946. Darker shades correspond to a larger communist vs catholic vote (black indicates a missing observation). Overall, the figure suggests that a longer German occupation is associated with left-wing radicalism, compared to what happens below the line.

The formal RDD tests reported in Table 3 confirm this visual impression. Electoral outcomes refer to the 1946 election for the constitutional assembly and the 1948 national election. In 1946 the Communist Party ran alone, while in 1948 it merged with the Socialist Party. For the sake of comparison, we also report the sum of socialist and communist votes in 1946. As noted above, we always include region fixed effects and the vote shares of Communists and Socialists, and of the Catholics, in 1919, 1921 and 1924.

The results are very stark. For all estimation methods and for all indicators, the average vote share of the Communist Party (or of Communists and Socialists together) is significantly larger above the Gothic line. The size of the RDD coefficient is also large, generally 6-10 percentage points, depending on the estimation method and the outcome measure. Within 50 Km of the Gothic line, the Communist Party obtained on average about 36.8% of the votes, thus the effect of being above the line corresponds to around 20% of the average vote share. Taking into account that being just North vs just South of the line corresponds to an additional half year of occupation, if the effect was linear in time, one more year of Nazi occupation would increase the vote share of the extreme left by 40%. This is approximately four times as much as the effect estimated in the above OLS regressions. Note that the effect of being North of the line is stronger on the communist votes alone than on the communist and socialist votes combined, suggesting that the effect is capturing a shift from the Socialist Party to the

²³As discussed below, we also do not find any significant unbalance in the presence of partisan brigades.

Table 3: **RDD Causal Effects – Electoral Outcomes**

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line. Robust standard errors are displayed in parentheses for polynomial regressions. Robust-bias adjusted 95% confidence intervals are displayed in parentheses for local RDD. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. *Communist* corresponds to the vote share of the Italian Communist Party (PCI); *Communist and Socialist* corresponds to the Popular Front (FP) in 1948, and for comparison we compute also *Communist and Socialist* in 1946 as Italian Communist Party (PCI) + Italian Socialist Party (PSI); *Catholic* corresponds to the Christian Democrats (DC); *Right-Wing* corresponds to Movimento Sociale Italiano (MSI) plus smaller parties supporting monarchy. Estimates are conditional on the 1919, 1921, and 1924 vote shares of *Catholic* and *Communist and Socialist*.

extreme left, consistently with the hypothesis that longer exposure to the Nazi occupation made some left-wing voters more extreme in their views.

The larger communist vote is also at the expense of the moderate catholic party. According to the estimates, the catholic vote share is systematically lower above the Gothic line, particularly in the 1948 election when the effect of being North of the line varies between -4 and -8 percentage points (4 percentage points correspond to about 7% of the catholic vote share within 50 Km of the Gothic line). The vote share for the extreme right is balanced around the Gothic line in both 1946 and 1948. Note that the estimated gain in the communist vote is generally larger than the catholic loss, implying

that other parties (the Socialist Party or other centrist parties) lost votes to the Communists North of the line.²⁴ Thus, overall the longer Nazi occupation and civil war induced a shift from the center and from the moderate left to the extreme left in the immediate postwar elections, with no corresponding shift to the extreme right.

Replacing region with province fixed effects has negligible effects on the estimates (Appendix Table C.9). Estimates not conditional on postwar vote shares are qualitatively similar or have larger estimated coefficients (see Appendix Table C.10).²⁵ Appendix Figure C.3 illustrates graphically the main polynomial regressions reported in Table 3, using a second order polynomial to fit the data. Each dot represents the average vote share in municipalities within 10 Km intervals North/South of the Gothic line. A discontinuity is visible, and it is particularly strong for the communist vote.

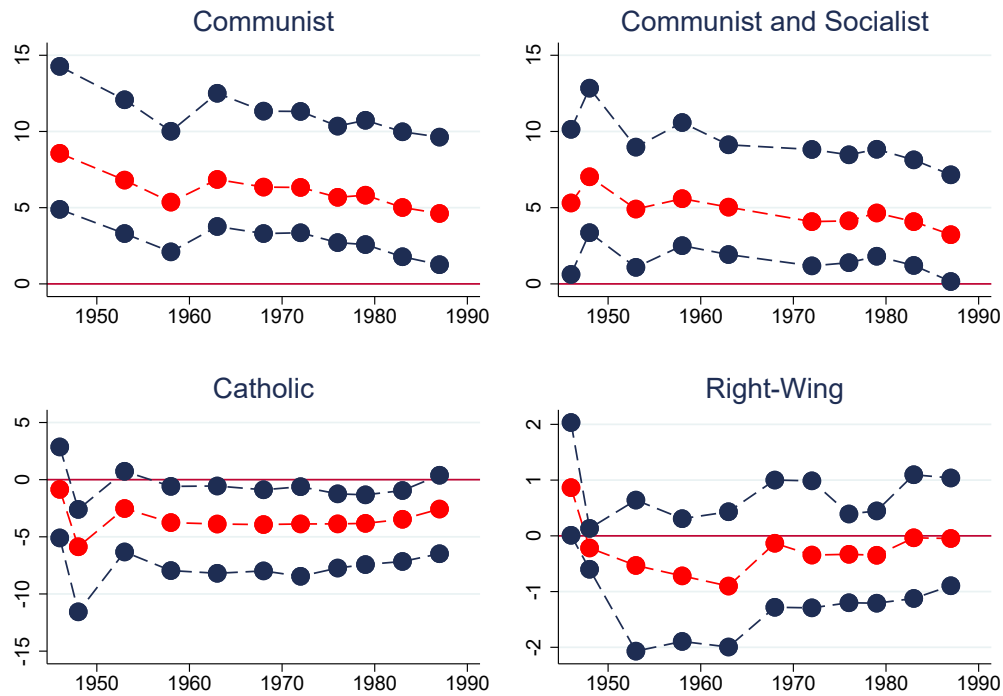

These political effects lasted until the end of the First Republic in the early 1990s. Figure 3 illustrates the pattern of RDD coefficients and confidence intervals for all elections between 1946 and 1987, estimated by local linear regressions conditioning on prewar election outcomes and region fixed effects (the last column in Table 3). As shown in Appendix Figure C.4, results are very similar when conditioning on province (rather than region) fixed effects. The left-wing parties retain a gain above the Gothic line, that shrinks from about 9 to 5 percentage points in the late 1980s and remains statistically different from zero for several decades. The catholic party bears a loss of votes of 4-5 percentage points, also declining slightly in absolute value and statistically significant throughout much of the period. The extreme right-wing parties also lose votes above the line, but only from the 1950s onwards, and this effect too is quite persistent. Overall, the political effects of being exposed to a longer Nazi occupation North of the Gothic line are very large and persistent.

Additional robustness checks. In Appendix B we report various robustness checks. Voting outcomes exhibit some patterns in the East-West direction. We thus want to be sure that the RDD estimates only reflect the impact of being North vs South of the line, without being contaminated by other geographic patterns in the data. For this purpose, we perform a number of robustness checks. First, we

²⁴The vote share of the small (centrist) Republican party is also lower by about 2-3 percentage points North of the line, while there is no significant discontinuity in voters' turnout (results available upon request).

²⁵Similarly, if we add as regressors all the control variables included in Table 2 (share of illiterate 1921 and 1951, population density 1921 and 1951, latitude, longitude, maximum altitude in the municipality, elevation city hall), in addition to region fixed effects and prewar vote shares, the estimates do not change (results available upon request).

Figure 3: Long-Term Persistence – RDD – Electoral Outcomes

Note: Coefficients and 95% robust-bias adjusted confidence intervals, estimated by local linear regressions as in the last column of Table 3, for all national elections from 1946 to 1987 and controlling for prewar electoral results and Region Fixed Effects. Data for the Communist Party are missing in 1948 as it ran with the Socialist Party.

estimate the same regressions with a first and second-degree spline polynomial in distance that also includes as regressors a first and second-degree polynomial in latitude and longitude, as well as the interaction of latitude and longitude and the same interaction squared. All results remain very similar, as shown in Appendix Table C.11. Second, we split the Gothic line in 25 Km intervals and we test our hypothesis including fixed effects for each interval (here we omit the region fixed effects). Appendix Table C.12 displays the results. All estimates are robust in terms of significance and magnitude.

Appendix Figure C.5 reports placebo tests for the main variables of interest to test whether our results might be attributed to random chance rather than a true causal effect. We shifted the location of the Gothic line North or South of its true position. Estimation is by local linear regression as in the last column of Table 3. The results indicate a clear discontinuity in the estimated coefficient at the true location of the Gothic line, but not at the fake discontinuities. We also estimated the same placebo tests on prewar electoral outcomes. Here no clear pattern is evident, and the true location of

the Gothic line generally does not stand out relative to the other position – see Appendix Figure C.6. This again corroborates the conclusion that no structural unbalance of pre-treatment political attitudes is evident.

The main results are also robust to the method of dealing with missing observations. Appendix Table C.13 restricts the sample by only including municipalities for which we have data on all three prewar elections (thus avoiding any imputation), and the results remain very similar.

Finally, there is generally no evidence of amplification effects, meaning that the treatment effect of being North of the line is homogeneous across municipalities, irrespective of their prewar vote share, whether there were more citizens under surveillance or whether they gave birth to a partisan (results available upon request). This too supports our identification strategy, because it suggests that the results do not reflect pre-existing trends.

Overall, these robustness checks confirm that the positive effect on the communist vote share is very robust, while the inference that the increase in the communist vote is only at the expense of the catholic vote (rather than also at the expense of the Socialists or of other moderate parties) is more sensitive to the sample and to the estimation method.

6.3 Mechanisms and contextual factors

How could the prolonged German occupation and associated civil war have such important political effects? We now address this question, reporting the RDD estimates for alternative contextual factors as outcomes.

Partisan brigades. As discussed above, partisan brigades were disproportionately associated with the Communist Party. This might give an advantage to the Communist Party, who could exploit their grassroots network to build local party organizations. The Nazi occupation might have enhanced this advantage because partisan brigades remained operative for longer North of the line.

We have already seen that the OLS regressions do not support this argument, since the presence of brigades is not correlated with election outcomes as soon as we control for past election results. More importantly, similar negative results hold when comparing outcomes above and below the Gothic line. Table 4 considers as a proxy of partisan activity around the Gothic line the presence of partisan

brigades (left-wing or other).²⁶ All of these outcomes are balanced around the Gothic line, except for the presence of non left-wing brigades, which seems higher South of the line. Similarly, as shown in Appendix C, municipalities that were birthplaces of a partisan are balanced around the Gothic line. These results are also apparent from Appendix Figures C.7 and C.8.

Table 4: **RDD Contextual Factors – Presence of Partisan Brigades**

	Polynomial Regression				Local RDD
	First order		Second order		
	50 Km	100 Km	50 Km	100 Km	
Presence of partisan brigades	-0.147 (0.121) 275	0.103 (0.096) 742	-0.311 (0.186)* 275	-0.120 (0.128) 742	-0.220 [-0.562;-0.008]** 260
Presence of left-wing partisan brigades	0.004 (0.127) 275	0.165 (0.098)* 742	-0.169 (0.188) 275	0.054 (0.132) 742	-0.074 [-0.435;0.160] 241
Presence of other partisan brigades	-0.152 (0.069)** 275	-0.063 (0.052) 742	-0.142 (0.067)** 275	-0.173 (0.070)** 742	-0.146 [-0.293;-0.050]*** 378

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line. Robust standard errors are displayed in parentheses for polynomial regressions. Robust-bias adjusted 95% confidence intervals are displayed in parentheses for local RDD. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. *Presence of partisan brigades*: Dummy equal to 1 if the area of the municipality intersects the area of operation of the partisan brigade (left-wing or other). See Appendix A for a description of left-wing vs other partisan brigades, and for data sources.

Next, we ask whether the presence of active brigades amplified the effect of a longer Nazi occupation in favor of the Communist Party, distinguishing between left-wing and other (mainly catholic) brigades. There are two reasons for asking this question. First, if the Nazi occupation strengthened grassroots organizations of the Communist Party through the resistance movement, this effect should be stronger where left-wing brigades were active. Second, whereas the Communist Party was generally associated with the resistance movement, this was not true for the catholic party, whose involvement with partisan activities was more haphazard. Where catholic brigades were active, however, local residents more easily associated the resistance movement with the catholic party. If indeed the mechanism behind our findings is that longer exposure to conflict induces voters to identify with and reward belligerent parties, we should observe the catholic party not lose votes (or gain votes) above the Gothic line if catholic brigades were active in that area. This positive association between active

²⁶We obtain the same results (available upon request) using the closest distance to partisan brigades (left-wing or other).

brigades and vote shares above the line is not necessarily to be expected for the Communist Party, which was generally perceived to be the main force behind the resistance movement irrespective of where its brigades were present.²⁷

This is indeed what we find in Table 5. First of all, the estimated coefficient of the interaction between the presence of a left-wing brigade and being North of the line is insignificant when the outcome is the communist vote share. Thus, the presence of left-wing partisan brigades had no impact on the effect of a longer Nazi occupation on the vote shares of the Communists. This finding is inconsistent with the idea that a longer Nazi occupation favored the Communist Party because it exploited the partisan brigades to build grassroots local organizations.

Second, the presence of other brigades (which for the most part were catholic) is associated with a significantly greater vote share of the catholic party North of the line (and a lower but insignificant vote share of the Communist Party).²⁸ Given the small sample size of the areas with non left-wing brigades and the volatility of the heterogeneity results, we do not want to overemphasize these findings. Nevertheless, they are consistent with the idea that voters reward the winning factions when they are perceived as belligerent and contributing to the victory, irrespective of whether or not they are extremist. In practice, however, this mechanism benefits extremist parties on the winning side, because they have a comparative advantage in organizing conflict, compared to more moderate parties.

Violence. Finally, we ask whether Nazi violence was higher North of the line. The recorded episodes only capture some of the violence actually borne by civilians. In particular, forced labor, evacuations of villages, and deportations are not included in our classification of episodes of violence. These other forms of violence were probably more diffuse North of the line, where the occupation lasted longer. Even where the violence did not actually occur, the threat of being hurt and the stress

²⁷Our assumption here is that, given the collective prior that the Communist Party is more active in fighting the Nazis, a communist brigade does not update the beliefs of the local population about who is fighting, while a catholic brigade does. Hence, the presence of a communist brigade can be interpreted solely as an organizational factor, but that is not the case for catholic brigades which could be interpreted as factors affecting both organizations and political attitudes.

²⁸Results are similar when looking at 100 km from the Gothic line (available upon request). As explained in Appendix A.2, non-left-wing brigades mostly consisted of *Brigate Fiamme Verdi*, a catholic organization, plus rarely some residual categories. Within 50 km of the Gothic line there are: 110 municipalities with at least one left-wing active brigade, 65 of these municipalities are North of the Gothic line; 20 municipalities with at least one non left-wing active brigade, 9 of these municipalities are North of the Gothic line. Non-left-wing brigades are not present in municipalities within 50 km North of the Gothic line where Right-wing Parties vote shares in 1946 and 1948 are not missing.

Table 5: RDD Causal Effects by Presence of Partisan Brigades – Electoral Outcomes

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line (column up) and the interaction between a dummy for the presence of a left-wing/not left brigade and being North of the line. Robust standard errors are displayed in parentheses. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. *Communist* corresponds to the vote share of the Italian Communist Party (PCI); *Communist and Socialist* corresponds to the Popular Front (FP) in 1948, and for comparison we compute also *Communist and Socialist* in 1946 as Italian Communist Party (PCI) + Italian Socialist Party (PSI); *Catholic* corresponds to the Christian Democrats (DC); *Right-Wing* corresponds to Movimento Sociale Italiano (MSI) plus smaller parties supporting monarchy. Estimates are conditional on the 1919, 1921, and 1924 vote shares of *Catholic* and *Communist and Socialist*. Not left-wing brigades not present in municipalities within 50 km North of the Gothic line where Right parties vote shares in 1946 and 1948 is not missing.

of the foreign occupation lasted longer North of the line, and this too could be reflected in political attitudes.

To capture at least some of these other forms of violence, in Panel A of Table 6 the outcome refers to the number of deported individuals arrested in the municipality. The estimated coefficient is almost always positive and, even if not always significant, it suggests that there were more deportations North of the line.

Table 6 reports also RDD estimates for the occurrence of at least one episode of German or fascist violence in the municipality, disaggregated by whether they occurred before or after the end of October 1944, that is, the month when the Allies stopped South of the Gothic line. We get similar results when we distinguish episodes by whether a majority of the victims were partisans or civilians (results available upon request).

Episodes of violence dated after October 1944 are significantly more widespread above the line, as expected, but episodes dated October 1944 or earlier occur more frequently below the line (the Germans also committed several atrocities during their retreat in the Summer of 1944). As a result, the overall occurrence of at least one episode is roughly balanced around the Gothic line. However, late-in-the-conflict violence was both more indiscriminate and more politically connotated, since it was associated with a more ruthless phase of the war and with the birth of the Italian fascist action squads. On the whole, the overall evidence on contextual factors seems to corroborate our hypothesis H2 above, rather than H3.

Table 6: **RDD Contextual Factors – Episodes of Violence**

	Polynomial Regression				Local RDD
	First order		Second order		
	50 Km	100 Km	50 Km	100 Km	
Panel A. Number of deported people arrested in the municipality

Entire Period (Jan. 1943-Aug. 1945)	-0.124 (0.079) 275	0.053 (0.072) 742	-0.129 (0.114) 275	-0.095 (0.085) 742	-0.127 [-0.339;0.043] 299

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line. Robust standard errors are displayed in parentheses for polynomial regressions. Robust-bias adjusted 95% confidence intervals are displayed in parentheses for local RDD. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. *At least one violence episode*: Dummy equal to 1 if records report at least one episode of violence. January 1943–August 1945 is the entire period for which we have episodes recorded. January 1943–October 1944 (November 1944–August 1945) is the period before (after) the battlefront moved to the Gothic line.

7 Survey data

To assess whether the legacy of the Nazi occupation is still detectable, in November-December 2015 we conducted a survey of residents near the Gothic line. Our goal is to explore whether left-wing respondents today have a stronger memory of the civil war, and whether this memory is stronger

North of the line, where the civil war lasted longer and was more intense. We interviewed 2,525 individuals, with at least 20 years of residence in their current municipality and above 40 years of age. The survey was conducted in 242 municipalities within 50 Km from the Gothic line (137 above and 105 below the line). All municipalities had a population of less than 25,000 inhabitants in 2011, and at least 7 individuals were interviewed in each municipality. The telephone interview lasted on average about 10 minutes, and contained about 30 questions (see the Appendix Tables C.14 and C.15).

We start by exploring the correlations between individual political positions and the memory of the civil war in the whole sample of respondents. OLS estimates are shown in Appendix Table C.16. In columns (1) and (2), the dependent variable is a dummy variable that equals one if the individual political position is left or center-left, and estimation is by Probit. In columns (3) and (4) estimation is by ordered Probit, and the dependent variable equals 2 if the political position is left, 1 if center-left, and 0 otherwise. Throughout we control for gender, age, years of education, and dummy variables for homeownership, college education, having children, vital record, being North of the Gothic line and 1921 Region fixed effects. As expected, individuals with a family member who took part in the civil war, or who suffered from WWII violence, or living in a municipality that commemorated the resistance are more likely to be on the left, irrespective of the specification. A left-wing position is also more likely if political attitudes when young were congruent with their father's position. Altogether these results suggest that a left-wing position is indeed more likely for individuals who retain a stronger memory of the civil war, and indirectly support the idea that longer exposure to the civil war left a persistent mark on political attitudes in favor of the Communist Party.

Next, we consider RDD estimates, comparing residents in municipalities above and below the Gothic line. Appendix Table C.17 reports balance tests around the Gothic for several socio-demographic variables and for political preferences. All variables are balanced, except perhaps a slight unbalance in sex, age and marital status, which anyway is not robust across estimation methods. There is also no evidence that today respondents North of the line are more likely to vote left, compared to those South of the line. This difference between our survey and the historical voting outcomes is likely to reflect the evolution of the Italian political system in the Second Republic (the Communist Party no longer exists, and its current re-incarnation, the Democratic Party, is a moderate party).

Consistently with these results, Figure C.9 shows that center-left and left-wing parties' vote shares are balanced North and South of the line for electoral results between 1992 and 2013. The same is true for center-right and right-wing parties. A slight imbalance is still present in centrist parties, mainly driven by *Democrazia Cristiana* in 1992, *Partito Popolare Italiano* and *Patto Segni* in 1994. These parties were close to what we define as *Catholics* in Table 3. This additional evidence suggests that the impact of violence on politics is highly persistent until a new major shock (such as the breakdown of the party system in 1992) kicks in.

Panel A of Appendix Table C.18 shows that the memory of the Civil war is stronger North of the Gothic line. Although the memory of violence is balanced around the line, respondents North of the line are more likely to say that one of their family members took part in the civil war, in general, or as a partisan, and are more likely to have participated in an event commemorating the resistance. Recall that, by Table 4, left-wing partisan brigades were equally spread out above and below the Gothic line. Hence, the survey results suggest that the civil war is still more salient and more vivid in the memory of current residents North of the line.

In the same spirit, we attempted to elicit anti-German sentiments by asking questions on wedding preferences by nationality, and questions on the Euro. Panel B presents the RDD estimates, after recoding all the variables so that a positive coefficient indicates anti-German sentiment North of the line. All estimates have the expected positive sign, except for wedding preferences of French vs German. Only a few of them are statistically significant, however, suggesting only weak evidence of more anti-German sentiments.

8 Conclusion

The civil war and the Nazi occupation of Italy occurred at a critical historical juncture, just before the birth of a new democracy and the emergence of a new party system. For the first time in a generation, Italian citizens were choosing political affiliations and forming political identities. We exploit the geographic heterogeneity in the duration and occurrence of the Nazi occupation and of the civil war, to study how these traumatic events shaped the newly-born political system.

Our main finding is that, where the foreign occupation and the civil war lasted longer and were

more intense, the radical left emerged as a much stronger political force. This effect was not just a temporary reaction to war traumas but persisted until the late 1980s.

What accounts for this large impact? And why is it so persistent? We discuss two alternative explanations. They both revolve around the fact that the Communist Party was more active in the resistance movement. The first explanation stresses individual political attitudes. In reaction to longer and more intense exposure to the violent Nazi occupation, voters identified with the radical political forces that stood up more forcefully against the enemy, and that in the end won the civil war. The second explanation emphasizes party organizations: the partisan brigades gave the Communists an advantage in building grassroots political organizations in the areas where the resistance movement was active for longer.

Although not conclusive, our evidence is more consistent with the first mechanism, operating through voters' attitudes and identities. First, there is no correlation between the presence of left-wing partisan brigades and voting outcomes; this is true both in the OLS regressions and in the RDD estimates. Second, the pro-Mussolini right-wing parties turned out to be slightly weaker, not stronger, in the areas under Nazi occupation. Furthermore, other pieces of evidence support a demand-side mechanism. First, in the sample of all Italian municipalities, the communist vote share is correlated with two indicators of Nazi violence (the occurrence of episodes of violence by Germans or fascists, and the location of two very violent elite German divisions). Violence episodes are also larger North of the line in the final phase of WWII when the civil war was harsher—although violence throughout all war years is balanced around the line. Second, a survey conducted in 2015 in municipalities around the Gothic line reveals that individuals with stronger memory of the civil war are more likely to lean to the left. Moreover, there is a stronger memory of the civil war in the municipalities above the line, which endured a longer Nazi occupation.

Overall, our results have several implications of general interest. First, civil war and widespread political violence reshape political identities in favor of the political groups that emerge as winners from the struggle and are perceived as having participated in the war. Since more extremist political forces have a comparative advantage in organizing violent conflict, they tend to benefit from these violent events. Second, these effects are very long-lasting and persist even when the cleavages that

gave rise to the civil war have disappeared. Third, these findings indirectly support an approach to voters' behavior that has a well-established tradition in political science (e.g., [Campbell et al., 1960](#) and [Achen and Bartels, 2016](#)), but is more at odds with conventional theories in political economics. Citizens vote for the parties with which they identify on cultural, moral, or social grounds. Political identification, in turn, is also shaped by intense and widely shared emotional experiences, and once formed it evolves slowly over time.

A Online Appendix – Data Sources and Description

The unit of observation is the municipality. We excluded the small region of Aosta Valley from our sample, because it always had a different electoral system. Moreover, its political scene has always been dominated by local parties. Geographic analysis used the Geographical Information Software (GIS) on the Italian 2001 administrative division map for what concerns municipalities structure (Source: ISTAT). In the main analysis we include 1921 Province or Region Fixed effects (Source: Elesh.it)

A.1 Political outcomes

Prewar political variables: We collected data on political outcomes before the war, for the elections held in 1919, 1921, and 1924. Here the source is [Corbetta and Piretti \(2009\)](#), who carried out a serious and meticulous work of reconstruction for that period. The Communist Party was very small in the 1921 and 1924 elections (and it did not exist in 1919), so we lump together the socialist and communist vote in the pre-fascist period using [Leoni \(2001\)](#) as reference. The right-wing vote cannot be separately measured in 1921, since fascists were running together with the more traditional and moderate liberals in that election. Hence for the pre-fascist period we only collect the *Catholic* and *Communist and Socialist* variables. Since there are several missing observations, in our baseline analysis we fill the missing observations in each election exploiting the remaining two elections plus additional observables. Thus, to fill the missing observations in, say, vote shares for Catholics in 1924 we impute predicted values of an OLS regression of the available vote shares on non-missing vote shares for Catholics in 1919 and/or 1921 plus the following observables: Population density in 1921, illiterate share in 1921 and province fixed effect. And similarly for 1919 and 1921 and when communists-socialist vote shares are missing. The parties in the *Catholic* definition are: In 1919 Partito Popolare Italiano; in 1921 Partito Cristiano del Lavoro; Partito Popolare Dissidente; Partito Popolare Italiano and Popolari Dissidenti; in 1924 Partito Popolare Italiano. The parties in the *Communist and Socialist* definition are: In 1919 Blocco Socialista Reformista-Repubblicano e dei Combattenti; Partito Radicale-Socialista-Repubblicano; Partito Sindacalista; Partito Socialista Indipendente; Partito So-

cialista Indipendente; Partito Socialista Italiano; Partito Socialista Riformista; Partito Socialista Ufficiale; Partito del Lavoro; Sindacato dell'Impiego; Socialisti Autonomi and Unione Socialista Italiana; in 1921 Partito Socialista Autonomo; Partito Socialista Indipendente; Partito Socialista Riformista; Partito Socialista Ufficiale; Partito Comunista and Partito Comunista d'Italia; in 1924 Partito Socialista Massimalista; Partito Socialista Ufficiale; Partito Socialista Unitario; Partito Comunista and Partito Comunista d'Italia.

Fascist presence variables: Thanks to [Acemoglu et al. \(2022\)](#) we have also information on fascist presence at municipality level. They construct fascist vote share in 1921 and in 1924 elections combining [Corbetta and Piretti \(2009\)](#), 1,200 local and national historical newspapers and local state archives. Moreover they construct a measure of violence (number of violent episodes per 1,000 inhabitants for the period 1920-1922) from [Franzinelli \(2003\)](#). Finally, they collected information on local branches of the Fascist Party in September 1921 from the prefect reports located in state archives throughout Italy from which a dummy for the presence of a Fascist branch is constructed.

Fascism period political variables: To proxy political attitudes before the civil war and after the last free election, we collect data on the number of citizens under surveillance for political reason (source: Casellario Politico Centrale).^{A.1} The original source reports the political affiliation, the municipality of residence and the year in which the citizen became under surveillance. We construct the share of *Left-wing citizens under surveillance* as the sum of communist, socialist or anti-fascism citizens under surveillance between 1925 and 1942 over 1921 population (x1000) for each municipality. As shown in Table 1, this variable correlates positively with *Communist and Socialist* prewar vote shares while it does not with *Catholic*. We also construct the variable *Other citizens under surveillance* as the sum of anarchic, republican and not available over 1921 population (x1000).

Moreover, from ANPI (National Association of Italian Partisans) we collected a list of 3,117 partisans with a short biography. This database is only a sample, but it was built to represent the political diversity of the resistance movement and includes almost all of the national and local leaders of the movement. From this source we create two dummy variables, for whether at least a partisan in our sample was born in the municipality, and for whether he/she was linked to a left-wing party in the

^{A.1}We thank Francesco Barilari for helping collecting these data.

postwar period. These variables capture the strength of local opposition to the fascist regime, rather than the presence of brigades in the area.

Postwar political variables: We measure political outcomes by the percentage of votes received by political parties at the 1946 election of the constitutional assembly, and in all subsequent 10 political elections for the Chamber of Deputies until 1987 (namely 1948, 1953, 1958, 1963, 1968, 1972, 1976, 1979, 1983 and 1987). Source: Italian Ministry of Interior. We consider three political groups. First the radical left, measured by the votes given to the Communist Party (Partito Comunista Italiano). We call this variable *Communist*. Since in 1946 the Communists and the Socialists (Partito Socialista Italiano) formed a single electoral list, the Popular Front, we also consider the votes received by these two parties together, and we call it *Communist and Socialist*. The second group is the Christian Democrats (Democrazia Cristiana), that we call *Catholic*. The third group, called *Right-wing*, consists of the Movimento Sociale Italiano (a party close to the fascists) and of smaller parties that supported the monarchy (namely: In 1946 Blocco Nazionale della Libertà, in 1948 and 1953 Partito Nazionale Monarchico, in 1958 Partito Nazionale Monarchico and Partito Monarchico Popolare, in 1963 and 1968 Partito Democratico Italiano di Unità Monarchica). Since we are interested in how the German occupation shifted political preferences from a moderate to an extreme left vote, we also compute the difference between the vote to Communist and the vote to catholic parties. This variable is called *Communist minus Catholic*.

Postwar political variables (1992 onwards): We further extend our analysis and consider the 7 national elections for the Chamber of Deputies from 1992 to 2013. Source: Italian Ministry of Interior. We consider five political groups: Extreme Left, Centre-Left, Centre, Centre-Right and Right. From 1996 onwards, the two major coalitions were represented by Centre-Left and Centre-Right. During these years the party names and coalitions changed multiple times: there are 320 recorded in the data, 244 did not get 1%. We report below the parties that reached at least 5% in a given election. The full split is available upon request. In 1992: Centre: DC; Centre-Left: PDS, PSI; Centre-Right: Lega Lombarda; Left-Wing: Rifondazione Comunista; Right Wing: MSI-DN. In 1994: Centre: P.Popolare Italiano; Centre-Left: PDS; Centre-Right: Forza Italia, Alleanza Nazionale, Lega Nord; Left-Wing: Rifondazione Comunista. In 1996: Centre-Left: PDS, Pop-Svp-Pri-Ud-

Prodi; Centre-Right: Forza Italia, Alleanza Nazionale, Lega Nord, CCD-CDU; Left Wing: Rifondazione Comunista. In 2001: Centre-Left: Democratici Sinistra, La Margherita; Centre-Right: Forza Italia, Alleanza Nazionale; Left-Wing: Rifondazione Comunista; Centre: Unione Di Centro. In 2006: Centre-Left: L'Ulivo; Centre-Right: Forza Italia, Alleanza Nazionale; Left-Wing: Rifondazione Comunista. In 2008: Centre: Unione Di Centro; Centre-Left: Partito Democratico; Centre-Right: Il Popolo Della Liberta', Lega Nord; Centre: Scelta Civica Con Monti Per L'Italia. In 2013: Centre-Left: Partito Democratico; Centre-Right: Il Popolo Della Liberta'; Other: Movimento 5 Stelle.

A.2 War-related variables

Episodes of violence: We collected data on the number of episodes in each municipality, the date, and the number and kind of victims. The full data set includes: The number of violent episodes in each municipality (this is the variable used in Appendix Figure C.1); date and municipality; total number of victims by status (civilian, partisan, soldier). Although the meticulous work done by the authors of “Atlas of Nazi and fascist massacres”, since combining multiple sources entails the risk of double counting, and since counting the number of victims entails likely measurement error, our preferred measure is a dummy variable, that equals 1 if in the municipality (and interval of time where applicable) there was at least one episode of violence. We also consider dummy variables for whether the majority of victims were partisans or civilians.

Our source is the “Atlas of Nazi and fascist massacres” (ANPI-INSMLI, 2016).^{A.2} This database lists all the massacres and the individual murders of civilians and resistance fighters killed in Italy during Second World War (mainly after September 8, 1943) both by German soldiers and soldiers of the Italian Social Republic outside of the armed fights.^{A.3} These range from the first murders in the South to the withdrawal massacres committed in the days after the Liberation. The historical inquiry was conducted locally by more than ninety researchers under the supervision of a joint historical commission established by Italian and German governments in 2009. The commission used the results of previous studies of the same kind made in Apulia, Campania, Tuscany, Emilia Romagna, and Piedmont and used three main national common sources: (i) The database of violent crimes perpetrated

^{A.2}Data downloaded in April 2016.

^{A.3}The data span from February 1943 to May 1945, but only 21 out of 5,594 events are dated before September 1943.

against civilians during the German occupation of Italy, established by the Joint Historical Italian-German Commission and based on police reports stored in the Archives of the Historical Office of Army General Staff and the Historical Archives of the Carabinieri of Rome. (ii) The General Repository of war crime reports collected from 1945 by the Army Prosecutors office in Rome; this report was illegally dismissed in 1960 and was later recovered by the Parliamentary Commission of Inquiry while investigating on the reasons for the concealment of some files about Nazi-fascist crimes (14th Parliamentary term). (iii) The rulings and files of the judiciary proceedings debated in the Military courts during the last trial season (from 1994 until now).

This source was not immediately available to us, however. In a previous version we had started from a composite dataset that mainly relied on record of charges pressed to “Carabinieri” (Italian Police, [CSIT \(2012\)](#)), for violence episodes and massacres against Italian citizens and Allied personnel committed by Nazi-fascists forces in the period 1943-1945. We then integrated this source with the following additional sources: [Collotti, Sandri and Sessi \(2000\)](#) and [Collotti, Sandri and Sessi \(2006\)](#) and [Gentile \(2015\)](#).^{A.4} This last source is particularly rich and detailed, since besides the Italian sources, it also incorporates episodes of violence reported in the German War Archives. Since [CSIT \(2012\)](#) (and partially also the other sources) reports single murders, we had assumed that two murders happening in the same municipality at no more than three days of distance were part of the same episodes. In order to avoid bias due to the same event counted twice we manually eliminated double episodes reported by [CSIT \(2012\)](#) or any other sources with meticulous checks on possible discrepancies on the location, the date or the number of victims involved in each episode.

Once we got access to the “Atlas of Nazi and fascist massacres” we recognized that this new source was more uniform and coherent than our first composite dataset, and thus in the current draft we only rely on the new source, the Atlas. Nevertheless, to assess robustness to possible measurement error, we merged the two data sets (our old composite dataset and the new data from the Atlas), trying to avoid double counting. The results reported in the paper are very similar to those obtained in the replications with this merged data set.

^{A.4}We also consider [Matta \(1996\)](#) for robustness checks, however since he reported only partial information for each episode we excluded it from the main analysis

Line of conflict: Based on [Baldissara \(2000, figure 23\)](#), we have reconstructed the evolution of the battlefield around two main lines of conflicts, geo-referencing the corresponding maps: The Gustav line and the Gothic line. In both cases, a few months of adjustments before the final settlement of the battlefield have been necessary. [Figure 2](#) illustrates the evolution of the battlefield around the Gothic line. There are three demarcation lines. (i) The line labelled “Allies” is where the Allies stopped between August 1944 and mid-September 1944. (ii) The line labelled “Fall 1944” is the original Gothic line set up by the Germans. Between late August and mid-September 1944 the Allies succeeded in breaching this line (the so called operation “Olive”). (iii) The line labelled “Nov. 1944–Apr. 1945” is where the Germans managed to contain the US-British offensive. From the end of October onwards, the Allies and the Germans were fighting along this line. It was finally breached in April 1945. Our RDD analysis is on the Northern-most line “Nov. 1944–Apr. 1945”, which was held by the Germans for the longest period.

Years of occupation: Fraction (or multiples) of years of occupation by German troops. Data refer to provinces (all the municipalities in the same province have the same number of years of occupation), except for the provinces cut by a line of conflict (both for Gothic and Gustav line), where provincial data have been corrected as follows:

- For the municipalities above the line of conflict belonging to a province below the line, we assign the years of occupation of the closest province above the line.
- For the municipalities below the line of conflict belonging to a province above the line, we assign the years of occupation of the closest province below the line.

Definition of occupation: Physical presence of Nazi troops on the Italian territory, for military control or for defense against the Allies (for what concerns events after the Armistice of Cassibile). The starting date is the planning and constitution of the first Nazi troops of the Operation Achse (9 May 1943), after the end of the campaign of Tunisia. The aim of this operation was to react to the possible desertion of the Italian ally. Sources: Mainly [Baldissara \(2000\)](#). Minor adjustments have been made using province specific references.

Partisan Brigades: We geo-referenced the maps of [Baldissara \(2000\)](#) (figures 8, 12, 15, 16, 17, 18, 19) that report the area of activity of partisan brigades during World War II. We created a dummy variable for the presence of partisan brigades equal to one if the municipality partly overlaps with the area in which a partisan brigade was active during the conflict (*Presence of partisan brigades (Intersect)*) or whether the area of the municipality is contained entirely in the operation area of a brigade (*Presence of partisan brigades (Within)*). We also consider the minimum distance of each municipality city hall from the area of activity of each brigade. The brigades considered are the following:

- Left-wing brigades: Brigade Garibaldi (Italian Communist Party), brigade Matteotti (Italian Socialist Party) and brigade Giustizia e Libertà (Partito d’Azione).
- Other brigades: Brigade Fiamme Verdi (Christian Democrats) and residual autonomous brigades.

16th SS-Panzer-Grenadier-Division “Reichsfuhrer-SS” and “Hermann Goering” divisions

location: We coded the location of these two specific German divisions, particularly violent and responsible for a very large number of criminal episodes against civilians. We have records of the precise location of these troops throughout the Italian civil war. From this we construct a dummy variable that takes value 1 for the municipalities that are within 15 Km or 10 Km from where either of these divisions have been located (measured as distance between city halls). We restrict attention to those two specific divisions, discarding all the other SS or Luftwaffe divisions, since in the reconstruction made by our main source ([Gentile, 2015](#)) those are the troops responsible for the majority and most dramatic episodes (e.g., Sant’Anna di Stazzema, Marzabotto).

Deported: Number of political deportations to Germany by municipality of capture. Source: [Mantelli and Tranfaglia \(2013\)](#). We have data on only 6,500 individuals, out of about 40,000 deported.

A.3 Other city characteristics

Geographic variables: We collected data on city hall elevation, and on maximum and minimum elevation in the municipality. Source: National Institute of Statistics (ISTAT). We also created a grid of 25 Km width covering all the Italian territory.

Industrial plants per capita: We collected data on the number of industrial plants per capita in each municipality from the 1951 Census. Source: ISTAT. Thanks to [Fontana et al. \(2021\)](#), we got access to the number of industrial plants and workers in 1927, we divided both measures by population in 1921. Source: *Censimento Industriale 1927*, ISTAT.

Agricultural variables: Thanks to [Fontana et al. \(2021\)](#), we got access to the number of agricultural firms and workers in 1929, we divided both measures by population in 1921. We also got the number of livestock (again per capita in 1921) and the percentage of surface devoted to agricultural production. Source: *Catasto Agrario 1929*, ISTAT.

Population and illiterate share: We collected data on total resident population, population density and literacy rates (1911, 1921, and then 1951, 1961, 1971, 1981 and 1991). Census were easily available only from 1971 onwards. For all the other Censuses we manually digitalized the data. Source: ISTAT.

A.4 Structure of Italian municipalities

The administrative structure in Italy changed over the years. In 1948 there were 7,392 municipalities, in 2001 the number had increased to 8,100. In order to build a time consistent panel, we took 2001 as the reference year. For all the years different from 2001 we performed the following adjustments:

- Change the names: Some municipalities changed their names, the main reason was to avoid confusion; names must be mapped in order to have a complete series for each municipality. One example is Madesimo in province of Sondrio that before 1983 was called Isolato.
- Consider aggregations (i): Some municipalities merged into a single entity. For instance, at date t we observe municipalities A and B , but at date $t' > t$, we observe municipality C corresponding to the merger of A and B . In 2001 we only observe municipality C . Then only municipality C is included in the sample. For date t when C did not exist yet, we impute to C the data of $A + B$.
- Consider partial aggregations (ii): It may be that some municipalities absorb a municipality that no longer exists. For instance at date t we observe A , B and X , but at date $t' > t$, we observe

municipality A and B while territory of X has been split (not necessarily equally) between A and B . In 2001 we only observe municipality A and B . Then only municipalities A and B are included in the sample. For date t when also X existed, we impute data of X to both A and B ; that is, at date t , we impute $A = A + X$ and $B = B + X$

- Consider disaggregations (i): Some municipalities split their territory in two or more municipalities. This situation is quite common in Italy, since Fascism tried to reduce the administrative centres, while the number of municipalities increased in the postwar period. For instance, suppose that at date t we observe only municipality C , but at date $t' > t$, we observe municipalities A and B corresponding to the separation (not necessarily equally) of C . In 2001 we observe A and B , but not C . Then we include in the sample both A and B . For date t , when A and B did not exist yet, we impute to both of them the data of C ; that is, at t , we impute $A = C$, $B = C$.
- Consider partial disaggregations (ii): We also track the case where C still exists in 2001 but at $t' > t$ parts of C were dismembered to give birth to A and B , with C still existing today. In this case, for all date prior to t we impute $A = C$ and $B = C$.

We neglect changes in the boundaries that do not determine the end of a municipality or the birth of a new one, since they do not alter municipalities structures and since our variables mainly refer to shares. All these adjustments used records in ISTAT and Italian Agency of Revenue, tracking changes in the period of interest. The only exception are municipalities born from municipalities that still exist: In these cases we had to manually check each split. These adjustments were made for all data at the municipality level (Census and electoral data, but also episodes of violence). When a municipality has data imputed as described above, we retain only the shares (e.g., illiterate share) and we discard absolute values (e.g., total number of illiterates).

Reference year for Provinces and Regions is 1921. We use GIS files (source Elesh.it) to assign each 2001 municipality to historical administrative units. As a robustness we also considered 1931, 1945 and 2001 administrative boundaries and the results are similar.

B Online Appendix – Additional Results and Robustness

B.1 Multiple hypothesis testing

Given the numerous tests considered under the same treatment, a concern is that we may falsely reject at least some null hypothesis of no effect. A vast literature has tackled the issue of multiple hypothesis testing. We perform various tests on the most demanding specification (Column 4) of Table 3, for all outcomes reported in Figure 3 and all the variables tested in Table 4, Table 6, Appendix Table C.5 and Appendix Table C.6.^{B.1}

One of the most popular ways to deal with this issue is to control the familywise error rate (FWER), which is the probability of making any type I error^{B.2}. We calculate Westfall-Young (Westfall and Young, 1993) stepdown adjusted p-values, which also control the FWER and allow for dependence amongst p-values.^{B.3} This method uses bootstrap resampling to allow for dependence across outcomes.^{B.4}

We report results from Table 3, for all outcomes reported in Figure 3 in Appendix Table C.7. In Appendix Table C.8 of Table 4 (Panel A), Table 6 (Panel B), Appendix Table C.5 (Panel C) and Appendix Table C.6 (Panel D).^{B.5} In Column 1 we report the p-values from Column 4 of the corresponding table (i.e. p-values not corrected) while Column 2 reports p-values corrected following Westfall and Young (1993). Once accounting for the proposed pvalue corrections, the significance of all main results are preserved, reassuring us that results presented are not due to false rejections.

Joint test that no treatment has any effect A complementary approach, suggested in Young (2019), rather than adjusting each individual p-value for multiple testing, it conducts a joint test of the hypothesis that no treatment has any effect, and then uses the Westfall-Young approach to test this

^{B.1}Due to the complexity of these procedures it is too demanding to consider local linear regression with optimal bandwidth, as in Column 5.

^{B.2}An alternative approach would be to follow Anderson (2008) to compute sharpened False Discovery Rate (FDR) q-values. A drawback of this method is that it does not account for any correlations among the p-values.

^{B.3}Stata code available as `randcmd`

^{B.4}We report bootstrap-t as it is generally considered superior to the -c because its rejection probabilities converge more rapidly asymptotically to nominal size, Hall (1992). We consider 1999 randomization iterations

^{B.5}They are presented in two separate tables just for practical reasons, they were all considered simultaneously in the analysis.

across equations.^{B.6} Looking at randomization-t p-value for the Westfall-Young multiple testing test of the significance of any treatment measure in each equation as a whole is 0.04. We can then reject the hypothesis that no treatment has any effect.

B.2 Robustness checks

In this subsection, we discuss the robustness of the causal inference presented in Table 3.

As apparent from Appendix Figure C.2, voting outcomes exhibit some patterns in the East-West direction. We thus want to be sure that the RDD estimates only reflect the impact of being North vs South of the line, without being contaminated by other geographic patterns in the data. For this purpose, we perform a number of robustness checks. First, we estimate the same regressions with a first and second degree spline polynomial in distance that also includes as regressors a first and second degree polynomial in latitude and longitude, as well as the interaction of latitude and longitude and the same interaction squared. Region fixed effects are always included amongst the regressors. All results remain very similar, as shown in Appendix Table C.11.^{B.7}

Second, we split the Gothic line in 25 Km intervals and we test our hypothesis (again with spline polynomials and local linear regressions) including fixed effects for each interval (here we omit the region fixed effects). This is equivalent to comparing municipalities above and below the line within each of these 25 Km intervals. Appendix Table C.12 displays the results. All estimates are robust in terms of significance and magnitude.^{B.8}

Appendix Figure C.5 reports placebo tests for the main variables of interest to test whether our results might be attributed to random chance rather than a true causal effect. We shifted the location of the Gothic line North or South of its true position by 50 Km at a time, up to a distance of 250 Km. Estimation is by local linear regression as in the last column of Table 3. The results indicate a clear discontinuity in the estimated coefficient at the true location of the Gothic line, but not at the fake discontinuities. The catholic vote also displays a clear discontinuity. We also estimated the same

^{B.6}Stata code available as `randcmd`

^{B.7}Both in Appendix Table C.11 and C.12 results for *Right parties* suffer of small sample sizes when applying the optimal bandwidth, it may explain some non fully robust specifications.

^{B.8}As a further check, we included fixed effects for provinces or for the electoral districts in the RDD regressions (there are 6 electoral districts within 50 Km of the Gothic line, and the line cuts through 3 of them). The results are similar and available upon request.

placebo tests on prewar electoral outcomes. Here no clear pattern is evident, and the true location of the Gothic line generally does not stand out relative to the other position – see Appendix Figure C.6. This again corroborates the conclusion that no structural unbalance of pre-treatment political attitudes is evident.

Next, we assess the robustness of the results to the method of dealing with missing observations. In Appendix Table C.13 we only include municipalities for which we have data on all three prewar elections (thus avoiding any imputation). Here the RDD estimates reveal even stronger effects than in the default sample, for both communist and catholic vote shares, except for the Communists and Socialists combined in 1946.

Finally, there is no evidence of amplification effects, meaning that the treatment effect of being North of the line is homogeneous across municipalities, irrespective of their prewar vote share (Table 5) or of whether they gave birth to a partisan (results available upon request). This too supports our identification strategy, because it suggests that the results do not reflect pre-existing trends.

Overall, these robustness checks confirm that the positive effect on the communist vote share is very robust, while the inference that the increase in the communist vote is only at the expense of the catholic vote (rather than also at the expense of the Socialists or of other moderate parties) is more sensitive to the sample and to the estimation method.

C Online Appendix – Additional Tables and Figures

In this section, we report additional tables and figures, which contain descriptive statistics and robustness checks, and are also discussed in the paper.

-
- Appendix Table C.1 we show how the main explanatory variables in Table 2 are only weakly correlated.
- Appendix Table C.2 reports summary statistics of the variables in the entire sample; Appendix Table C.3 provides the same summary statistics for municipalities within a 50 Km radius around the Gothic line.
- Appendix Table C.4 shows in Column 1 that the relationship between the communist vote and days of occupation is non-linear. As the duration of the occupation increases, the positive relationship with the postwar electoral results is stronger. Moreover, all results are qualitatively similar or stronger if we restrict the sample to regions where the occupation lasted more than one year for at least one municipality (see column 2).
- Appendix Table C.5 reports balance tests for pre-treatment observables. Appendix Table C.6 considers prewar vote shares (Panel A), fascist presence variables (Panel B) and proxies of opposition to fascism after the last free elections and before the civil war (Panel C). Overall very few estimates are significant.
- Appendix Tables C.7 and C.8 address the concern that we may falsely reject at least some null hypothesis of no effect. The significance of all main results are preserved, reassuring us that the results presented are not due to false rejections.
- Appendix Table C.9 confirm the results presented in Table 3 when controlling for Province (as 1921) fixed effects: longer German occupation is associated with left-wing radicalism, compared to what happens below the line.

- Appendix Table C.10 confirm the results presented in Table 3 when not controlling for prewar electoral outcomes: longer German occupation is associated with left-wing radicalism, compared to what happens below the line.
- Appendix Table C.11 and Appendix Table C.12 confirm that RDD estimates only reflect the impact of being North vs South of the line, without being contaminated by other geographic patterns in the data (in particular on the East-West Dimension). Appendix Table C.11 estimate the same regressions as Table 3 with a first and second degree spline polynomial in distance that also includes as regressors a first and second degree polynomial in latitude and longitude, as well as the interaction of latitude and longitude and the same interaction squared. In Appendix Table C.12 Second, we split the Gothic line in 25 Km intervals and we test our hypothesis including fixed effects for each interval (here we omit the region fixed effects). All estimates are robust in terms of significance and magnitude.
- Appendix Table C.13 restricts the sample by only including municipalities for which we have data on all three prewar elections (thus avoiding any imputation), and the results remain very similar. We conclude that the main results are also robust to the method of dealing with missing observations.
- Appendix Table C.14 reports the detail of the questions of the survey presented in Section 7. Summary statistics are presented in Appendix Table C.15
- Appendix Table C.16 explores the correlations between individual political positions and the memory of the civil war in the whole sample of respondents. These results suggest that a left-wing position is indeed more likely for individuals who retain a stronger memory of the civil war, and indirectly support the idea that a longer exposure to the civil war left a persistent mark on political attitudes in favor of the Communist Party.
- Appendix Table C.17 reports balance tests around the Gothic for several socio-demographic variables and for political preferences. All variables are balanced.

- Appendix Table C.18 shows that the memory of the Civil war tends to be stronger North of the Gothic line. Appendix Table C.18 attempts to elicit anti-German sentiments. Only few results are statistically significant suggesting only weak evidence of more anti-German sentiments.
- Appendix Figure C.1 reports the number of violence episodes and the municipalities where two German divisions that were particularly violent and committed several crimes against civilians stopped. Visually we can observe a positive correlation between these two measures.
- In Appendix Figure C.2 we plot the difference between the communist and catholic vote shares in 1946. Overall, the figure suggests that a longer German occupation is associated with left-wing radicalism, compared to what happens below the line.
- Appendix Figure C.3 illustrates graphically the main polynomial regressions reported in Table 3, using a second order polynomial to fit the data. A discontinuity is visible, and it is particularly strong for the communist vote.
- Appendix Figure C.4 confirms results presented in Figure 3 when conditioning on province fixed effects. The left-wing parties retained a gain above the Gothic line while the catholic party bears a loss of votes. Overall, the political effects of being exposed to a longer Nazi occupation North of the Gothic line are very large and persistent.
- Appendix Figure C.5 reports placebo tests for the main variables of interest to test whether our results might be attributed to random chance rather than a true causal effect. We shifted the location of the Gothic line North or South of its true position. The results indicate a clear discontinuity in the estimated coefficient at the true location of the Gothic line, but not at the fake discontinuities. Similarly, Appendix Figure C.6 estimates the same placebo tests on prewar electoral outcomes. The results corroborates the conclusion that no structural unbalance of pre-treatment political attitudes is evident.
- Appendix Figure C.7 and C.8 visually confirm the observation presence of partisan is balanced North and South of the Gothic line.

- Appendix Figure C.9 extends Figure 3 from 1992 to 2013. It confirms that after major shocks (Fall of the Berlin Wall (1989), end of the URSS (1991), political corruption scandal “Mani Pulite” (1992-1994)) the effect of occupation and violence on political preferences is not present.

Table C.1: Correlations main explanatory variables

Variables	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
(1) Years of occupation	1								
(2) At least one episode of violence	0.127	1							
(3) Within 15 km of violent Nazi division	-0.203	0.218	1						
(4) Presence of left-wing partisan brigades	0.322	0.177	-0.048	1					
(5) Presence of other brigades than left-wing	0.065	0.078	0.012	-0.192	1				
(6) Birthplace of a partisan	0.054	0.26	0.125	0.059	0.006	1			
(7) Birthplace of a left-wing partisan	0.007	0.134	0.055	0.015	-0.003	0.395	1		
(8) Left-wing citizens under surveillance 1925-1942	0.113	0.093	0.073	0.011	0.034	0.178	0.144	1	
(9) Other citizens under surveillance 1925-1942	0.029	0.086	0.049	0.013	-0.003	0.127	0.156	0.276	1

Note: Correlation matrix between the duration of the Nazi occupation, measures the occurrence of violence and measures the presence of partisan brigades in the area of the municipality. *Years of occupation*: years of occupation measured at province level (see Appendix for exceptions). *At least one violence episode*: Dummy equal to 1 if records report at least one episode of violence in the period considered. *Within 15 Km of violent Nazi divisions*: Dummy equal to 1 if the minimum distance of the municipality from one occupied by either RFSS or HG Division is less than 15 Km (using city hall as reference point). *Presence of partisan brigades*: Dummy equal to 1 if the area of the municipality intersects the area of operation of the partisan brigade (left-wing or other).

Table C.2: Summary Statistics

Variable	Obs	Mean	Sd	Min	Max
Communist 1946 (%)	5,559	15.10	14.20	0.00	76.83
Socialist and Communist 1946 (%)	5,559	37.48	21.29	0.22	91.42
Catholic 1946 (%)	5,559	42.14	16.93	0.51	95.02
Right parties 1946 (%)	3,227	2.72	6.12	0.00	78.77
Socialist and Communist 1948 (%)	5,384	26.66	19.08	0.00	80.92
Catholic 1948 (%)	5,384	53.97	17.16	2.08	97.39
Right parties 1948 (%)	5,199	3.30	6.19	0.00	73.19
Socialist 1919 (%)	5,698	30.50	25.46	0.00	100.00
Catholic 1919 (%)	5,698	27.00	21.25	0.00	100.00
Socialist and Communist 1921 (%)	5,698	27.05	21.61	0.00	100.00
Catholic 1921 (%)	5,698	27.72	20.81	0.00	100.00

	112	112	64

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line on the sample of Italian municipalities with all the three political variables prewar (1919, 1921, 1924) not missing. Robust standard errors are displayed in parentheses for polynomial regressions. Robust-bias adjusted 95% confidence intervals are displayed in parentheses for local RDD. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. *Communist* corresponds to the vote share of the Italian Communist Party (PCI); *Communist and Socialist* corresponds to the Popular Front (FP) in 1948, and for comparison we compute also *Communist and Socialist* in 1946 as Italian Communist Party (PCI) + Italian Socialist Party (PSI); *Catholic* corresponds to the Christian Democrats (DC); *Right-Wing* corresponds to Movimento Sociale Italiano (MSI) plus smaller parties supporting monarchy. Estimates are conditional on the 1919, 1921, and 1924 vote shares of *Catholic* and *Communist and Socialist*.

Table C.14: Survey Data – Variables Description

Variable	Definition	Question	Answers
Male	Dummy for male respondent		
Years of age	Age of the respondent		
Years of residency	Duration of the residency in the municipality		
College level education	Dummy equal to 1 if highest educational attainment is at least college (answers 1 or 2)	What is the highest educational degree you obtained?	1 - PhD/Master – 2 - College – 3 - Senior High School – 4 - Junior High School – 5 - Primary School – 6 - Primary School not finished
Years of education	Number of years spent at school (inferred from the answer to the previous question)		
Married, widow(er), separated or divorced	Dummy equal to 1 if the respondent is married, widow(er), separated or divorced		
One or more children	Dummy equal to 1 if the respondent has at least one child		
House ownership	Dummy for house ownership		
Left-wing political preferences	Dummy for left-wing political preferences (answers 1 or 2)		
Center political preferences	Dummy for center political preferences (answer 3)		
Right-wing political preferences	Dummy for right-wing political preferences (answer 4 or 5)		
Independent political preferences	Dummy for independent political preferences (answer 6)	How would you define your political position with a single word?	1 - Left – 2 - Center-Left – 3 - Center – 4 - Center-Right – 5 - Right – 6 - Independent
Congruence with father's political preferences	Dummy for congruence with father's political preferences (answer 1)	How close were your vote to that of your father the first time you voted?	1 - Very close – 2 - Quite close – 3 - Not that close – 4 - Not close
One family member took part in the civil war	Dummy for the presence of a family member who took part in the civil war (answer 1 or 2)		
One family member took part in the civil war as a partisan	Dummy for the presence of a family member who took part in the civil war as a partisan (answer 1)	Do you remember, or were you told whether any member of your family took part in the civil war in the period 1943-1945? If so, as a partisan or as a Mussolini's supporter?	1 - Yes, as a partisan – 2 - Yes, as Mussolini's supporter – 3 - No
One family member was victim of violence during WWII	Dummy for the presence of a family member who was victim of violence during WWII (answer 1)	Do you remember, or were you told whether a member of your family was a victim of violence or deprivations during WWII? If so, from whom?	1 - Yes (add description) – 2 - No
The municipality organized an event to commemorate the Resistance	Dummy for the organisation of commemorating events in the municipality (answers 1 or 2)		
Participation to an event organized to commemorate the Resistance	Dummy for the participation to commemorating events in the municipality (answer 2)	Do you remember whether your municipality has ever organized an event to commemorate the Resistance and the Partisan war? If so, did you attend?	1 - Yes, but I did not attend – 2 - Yes, and I attended – 3 - No
Excessive German predominance in Europe	Dummy equal to 1 if the respondent agrees with excessive German predominance in Europe (answers 1 or 2)	How strongly do you agree with the statement "The Euro introduction has worsened the risk of an excessive German predominance in Europe"?	1 - Strongly Agree – 2 - Agree – 3 - Disagree – 4 - Strongly Disagree
The Euro was harmful for Italy	Dummy equal to 1 if the respondent believes that the introduction of Euro has been harmful to Italy (answers 1 or 2)	How strongly do you agree with the statement "The introduction of Euro in Italy has been positive for our country"?	1 - Strongly Agree – 2 - Agree – 3 - Disagree – 4 - Strongly Disagree
Wedding preference, Poland over Germany	Dummy for Poland ranked over Germany		
Wedding preference, UK over Germany	Dummy for UK ranked over Germany	I am going to present different nationalities. Would you tell, in order, for which ones of them you wouldn't be particularly happy in the event of the wedding of a relative with a person of that nationality.	1 - Poland – 2 - UK – 3 - Germany – 4 - France
Wedding preference, France over Germany	Dummy for France ranked over Germany		
Wedding preference, Germany ranked last	Dummy for Germany ranked last		

Note: The first column indicates the name of the variable used in the analysis. The second includes a brief description and, when appropriate, columns 3 and 4 contain the relevant survey question with possible answers. The original questionnaire was administered in Italian, the content has been translated to the benefit of non-Italian speakers.

Table C.15: Survey Data – Summary Statistics

Variable	Obs	Mean	Sd	Min	Max
Male	2,491	0.299	0.458	0	1
Years of age	2,467	66.136	11.245	41	95
Years of residency	2,443	52.449	17.613	20	95
College level education	2,119	0.088	0.283	0	1
Years of education	2,119	9.683	4.241	0	21
Married, widow(er), separated or divorced	2,112	0.911	0.286	0	1
One or more children	2,098	0.865	0.342	0	1
House ownership	2,029	0.934	0.248	0	1
Left-wing political preferences	1,970	0.424	0.494	0	1
Center political preferences	1,970	0.072	0.258	0	1
Right-wing political preferences	1,970	0.123	0.328	0	1
Independent political preferences	1,970	0.381	0.486	0	1
Congruence with father’s political preferences	1,713	0.779	0.415	0	1
One family member took part in the civil war	2,270	0.320	0.467	0	1
One family member was victim of violence during WWII	2,252	0.226	0.419	0	1
One family member took part in the civil war as a partisan	2,252	0.191	0.393	0	1
The municipality organized an event to commemorate the Resistance	2,226	0.704	0.456	0	1
Participation to an event organized to commemorate the Resistance	2,226	0.330	0.470	0	1
Excessive German predominance in Europe	1,940	0.308	0.462	0	1
The Euro was harmful for Italy	2,279	0.259	0.438	0	1
Wedding preference, Poland over Germany	1,054	0.275	0.447	0	1
Wedding preference, UK over Germany	1,066	0.604	0.489	0	1
Wedding preference, France over Germany	1,064	0.647	0.478	0	1
Wedding preference, Germany ranked last	1,081	0.189	0.391	0	1

Note: See Appendix Table C.14 for variables’ description.

Table C.16: Survey Data – Left-Wing Political Preferences

	left-wing preferences (a)		left-wing preferences (b)					
	(1)	(2)	Non-Left	Center-Left	Left	Non-Left	Center-Left	Left
Family member was victim of violence during WWII	0.142 (0.071)**	0.155 (0.072)**	-0.053 (0.026)**	0.009 (0.005)**	0.044 (0.021)**	-0.060 (0.026)**	0.011 (0.005)**	0.049 (0.021)**
Family member took part in the civil war	0.170 (0.078)**	0.205 (0.079)**	-0.062 (0.028)**	0.011 (0.005)**	0.051 (0.023)**	-0.075 (0.029)**	0.014 (0.005)**	0.061 (0.023)**

Wedding preference, Germany ranked last	0.058 (0.053) 1081	0.101 (0.076) 1081	0.067 [-0.141;0.277] 265

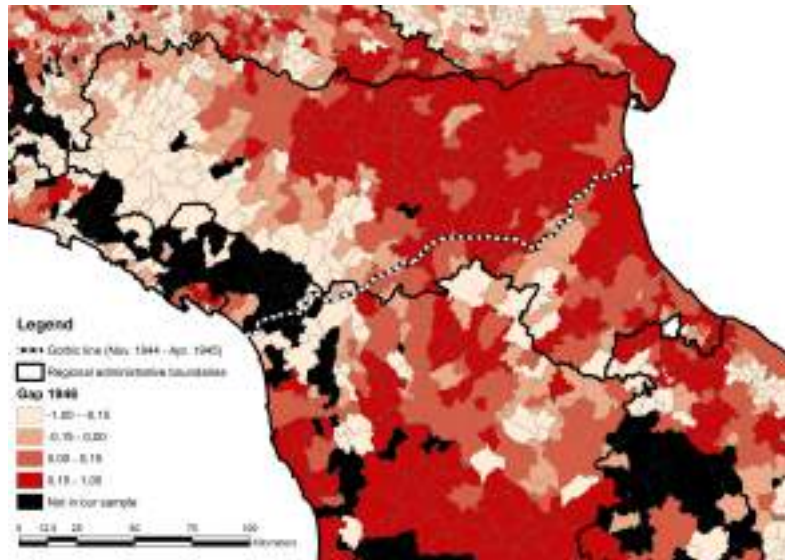

Note: RDD coefficients of being (just) above vs being (just) below the Gothic line. Robust standard errors are displayed in parentheses for polynomial regressions. Robust-bias adjusted 95% confidence intervals are displayed in parentheses for local RDD. Significance level: ***<0.01, **<0.05, *<0.1. Number of observations reported in each third row. Regressions include Region Fixed Effects. See Appendix Table C.14 for variables' description.

Figure C.1: Violence Episodes and Municipalities Occupied by “HG-RFSS”

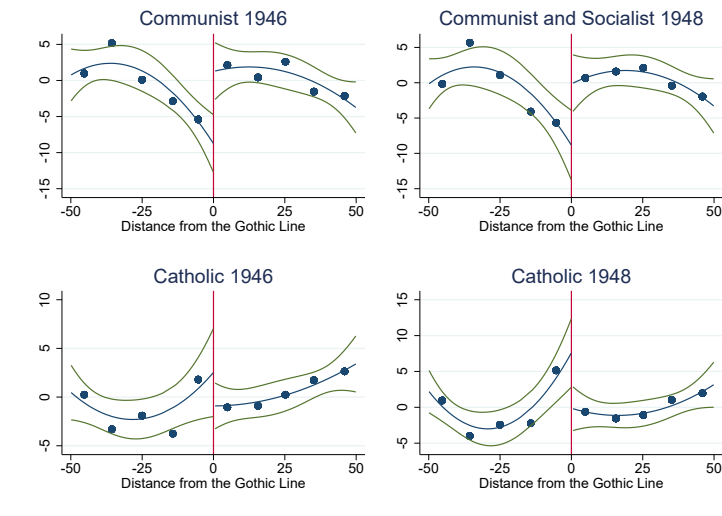

Note: Geographic distribution of violence episodes (by number/intensity) and of violent Nazi divisions (16th SS-Panzer-Grenadier-Division “Reichsfuhrer-SS” and “Hermann Goering”). See Appendix A for historical sources.

Figure C.2: Communist minus Catholic in 1946

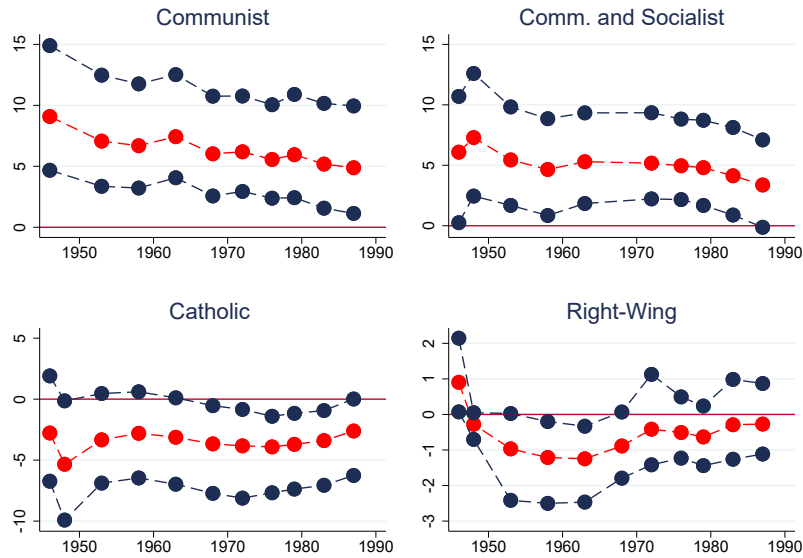

Note: Geographic distribution of the variable *Communist minus Catholic 1946*

Figure C.3: RDD Discontinuities – Electoral Outcomes

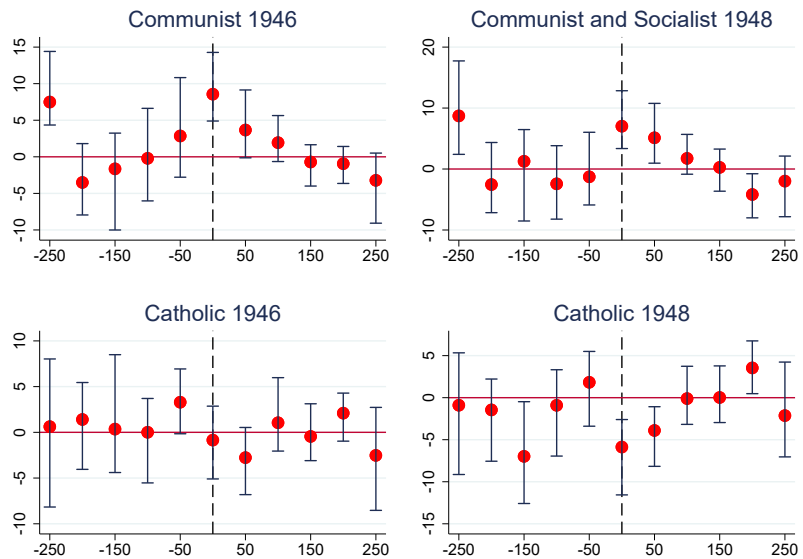

Note: Second order polynomial regressions at the 50 Km bandwidth shown in the second column of Table 3. Each dot corresponds to the average vote share for all municipalities within the corresponding 10 Km interval.

Figure C.4: Long-Term Persistence – RDD (Province Fixed Effects) – Electoral Outcomes

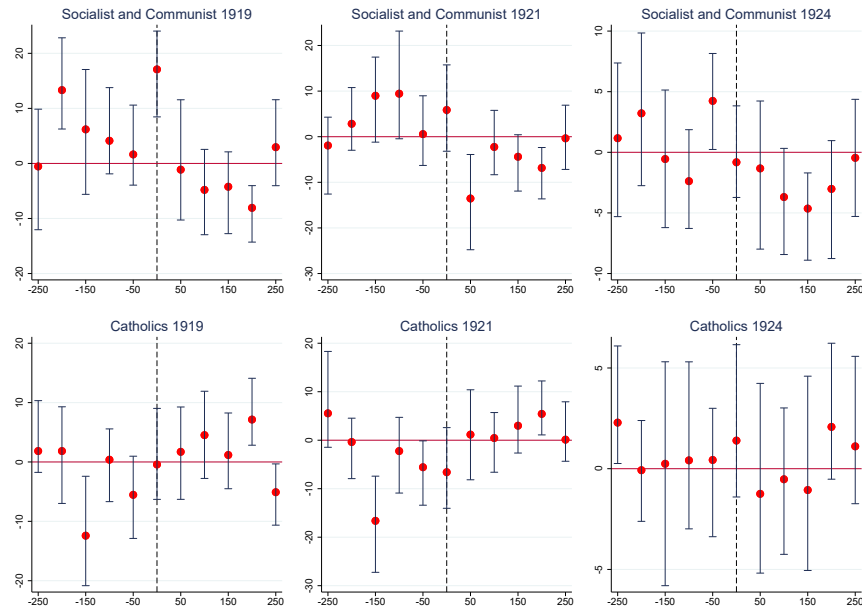

Note: Coefficients and 95% robust-bias adjusted confidence intervals, estimated by local linear regressions as in the last column of Table C.9, for all national elections from 1946 to 1987 and controlling for prewar electoral results. Data for the Communist Party are missing in 1948 as it ran with the Socialist Party.

Figure C.5: Placebo Coefficients – Postwar Elections

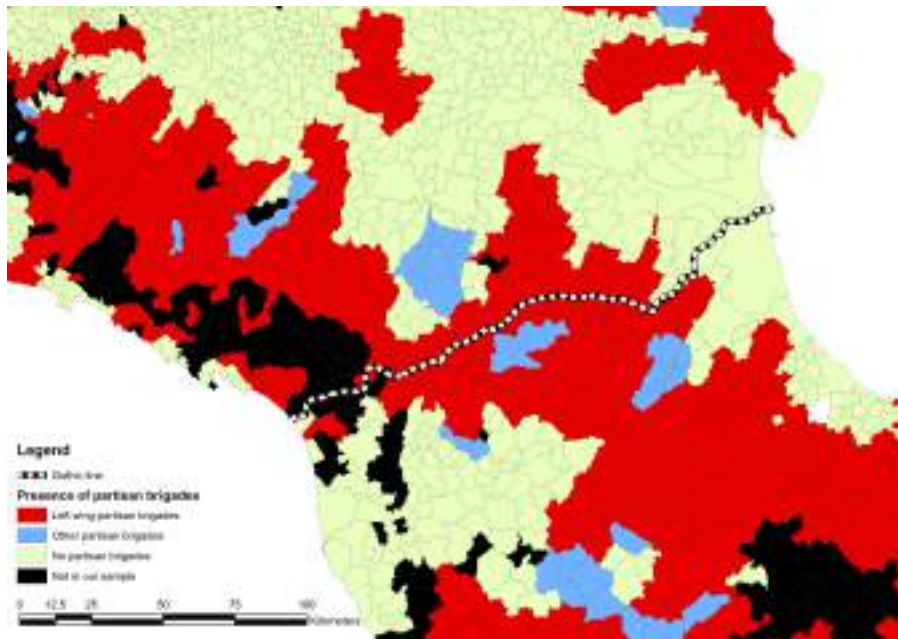

Note: Coefficients and 95% robust-bias adjusted confidence intervals, estimated by local linear regression as in the last column of Table 3, controlling for prewar electoral results and Region Fixed Effects, shifting the position of the Gothic line North or South of its true position by 50 Km at a time up to plus or minus 250 Km.

Figure C.6: Placebo Coefficients (50 Km) – Prewar Elections

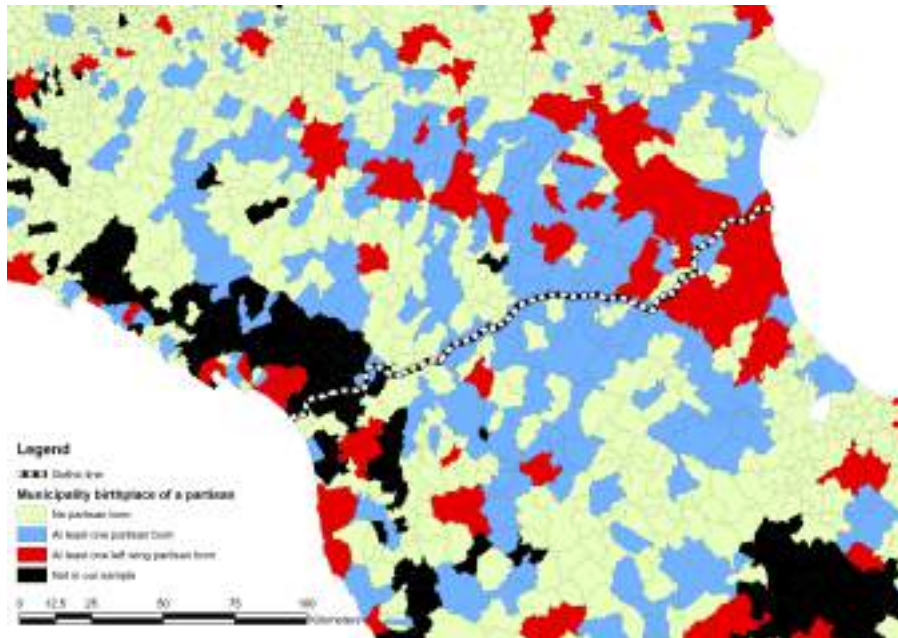

Note: Coefficients and 95% robust-bias adjusted confidence intervals, estimated by local linear regression as in the last column of Table C.6, including Region Fixed Effects, shifting the position of the Gothic line North or South of its true position by 50 Km at a time up to plus or minus 250 Km.

Figure C.7: Presence of Partisan Brigades

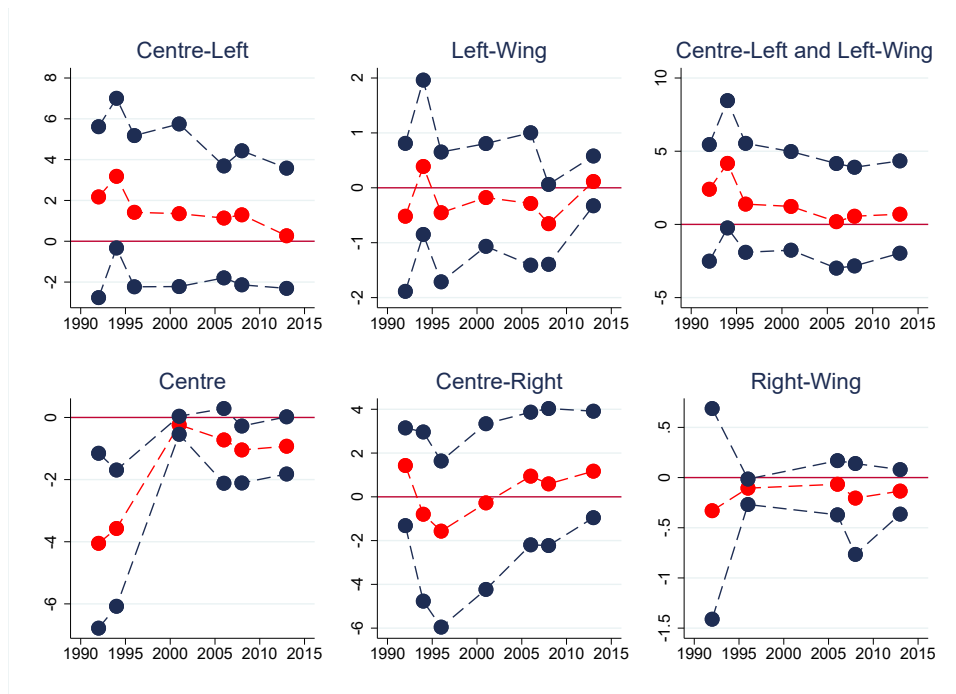

Note: Geographic distribution of left-wing and other partisan brigades. See Appendix A for historical sources.

Figure C.8: Municipality birthplace of a partisan

Note: Geographic distribution of birthplace of partisans. See Appendix A for historical sources.

Figure C.9: Long-Term Persistence – RDD – Electoral Outcomes 1992-2013

Note: Coefficients and 95% robust-bias adjusted confidence intervals, estimated by local linear regressions as in the last column of Table 2, and controlling for prewar electoral results and Region Fixed Effects. No Centre parties present in 1996, no Extreme Right parties present in 1994, 1998 and 2001.
