

Legal Investor Protection and Takeovers

MIKE BURKART, DENIS GROMB, HOLGER M. MUELLER,
and FAUSTO PANUNZI*

ABSTRACT

This paper examines the role of legal investor protection for the efficiency of the market for corporate control when bidders are financially constrained. In the model, stronger legal investor protection increases bidders' outside funding capacity. However, absent effective bidding competition, this does not improve efficiency, as the bid price, and thus bidders' need for funds, increases one-for-one with the pledgeable income. In contrast, under effective competition for the target, the increased outside funding capacity improves efficiency by making it less likely that more efficient but less wealthy bidders are outbid by less efficient but wealthier rivals.

BUILDING ON THE WORK of La Porta et al. (1997, 1998), several empirical studies show that countries with stronger legal investor protection allocate resources more efficiently. For instance, Wurgler (2000) shows that these countries increase investment more in growing industries, and decrease investment more in declining industries, compared to countries with weaker legal investor protection. Similarly, McLean, Zhang, and Zhao (2012) show that firms in these countries exhibit a higher sensitivity of investment to growth opportunities and consequently enjoy higher total factor productivity growth and higher profitability.

An important resource allocation mechanism is the takeover market. In the takeover market, both assets and managerial talent are reallocated across firms and industries. Indeed, consistent with the empirical evidence showing

DOI: 10.1111/jofi.12142

that countries with stronger legal investor protection allocate resources more efficiently, Rossi and Volpin (2004) find that these countries also have more active takeover markets.

Existing theory offers little guidance, however, as to *why* the takeover outcome might be more efficient in countries with stronger legal investor protection. There are two reasons for this. First, takeover models typically do not explicitly consider legal investor protection. Second, empirical research suggests that legal investor protection matters primarily because it relaxes financing constraints (e.g., La Porta et al. (1997), McLean, Zhang, and Zhao (2012)).¹ Yet, and in stark contrast to the standard corporate finance model of investment (e.g., Tirole (2006)), existing takeover models typically assume that bidders are *not* financially constrained (e.g., Grossman and Hart (1980, 1988), Shleifer and Vishny (1986), Hirshleifer and Titman (1990), Burkart, Gromb, and Panunzi (1998, 2000), Mueller and Panunzi (2004)).²

To shed light on this issue, we incorporate both legal investor protection and financing constraints into a standard takeover model à la Grossman and Hart (1980). In that model, no individual target shareholder perceives himself as pivotal for the outcome of a tender offer, leading to free-riding behavior. As a consequence, target shareholders tender only if the bid price reflects the full posttakeover share value (Bradley (1980), Grossman and Hart (1980)).³ However, if the bidder cannot make a profit on tendered shares, value-increasing takeovers may not take place. As Grossman and Hart argue, one way for the bidder to make a profit is by diverting corporate resources as private benefits after gaining control. Private benefits extraction lowers the posttakeover share value and thus the price that the bidder must offer target shareholders to induce them to tender.

¹ La Porta et al. (1997) show that countries with stronger legal investor protection have larger external capital markets and more IPOs. McLean, Zhang, and Zhao (2012) show that firms in such countries exhibit both a lower sensitivity of investment to cash flow, meaning they are less financially constrained, and a higher sensitivity of either equity or debt issuance to q , meaning firms with better investment opportunities are better able to raise outside funds.

² All these papers build on Grossman and Hart's (1980) seminal analysis of the free-rider problem in takeovers. While Chowdhry and Nanda (1993)—in a model that assumes no free-rider problem—and Mueller and Panunzi (2004) examine the strategic role of debt financing in takeovers, neither of these papers considers bidders' financing constraints. In particular, this implies that, in contrast to the standard corporate finance model of investment, bidders' own resources are immaterial for efficiency.

³ Rossi and Volpin (2004) provide empirical support for the free-rider hypothesis by showing that bid premia in tender offers are higher than in alternative takeover modes. They conclude (p. 293): "We interpret the finding on tender offers as evidence of the free-rider hypothesis: that is, the bidder in a tender offer needs to pay a higher premium to induce shareholders to tender their shares." In a recent empirical study, Bodnaruk et al. (2011) provide further evidence in support of the free-rider hypothesis. In particular, they show that (i) takeover premia are higher when the target's share ownership is more widely dispersed, and (ii) firms with more widely dispersed share ownership are less likely to become takeover targets. Both findings are consistent with finite-shareholder versions of the free-rider model (e.g., Bagnoli and Lipman (1988), Holmström and Nalebuff (1992), Gromb 1992)).

In our model, legal investor protection limits the ease with which the bidder, once in control, can divert corporate resources as private benefits. This has two main implications. First, it reduces the bidder's profit from the takeover, thus making efficient takeovers less likely. Second, it raises the posttakeover share value, thus increasing the bidder's pledgeable income and, by implication, his outside funding capacity. However, absent effective bidding competition, this increased outside funding capacity does not relax the bidder's budget constraint. As the bid price increases in lockstep with the posttakeover share value—to induce target shareholders to tender their shares—the bidder's *need* for funds increases one-for-one with his pledgeable income, offsetting any positive effect of legal investor protection on his outside funding capacity.

The conclusion that legal investor protection does not relax the bidder's budget constraint is disconcerting. After all, empirical research suggests that one of the main effects of legal investor protection is that it eases financing constraints. However, this conclusion follows naturally from any setting in which the bid price adjusts in lockstep with the posttakeover share value and thus with the bidder's pledgeable income. Turning this result on its head, if the bid price did *not* adjust in lockstep with the bidder's pledgeable income, then the positive effect of legal investor protection on the bidder's outside funding capacity might have implications for efficiency.

While several factors might break this one-for-one relationship between the bid price and the bidder's pledgeable income, here we focus on one that we think is particularly relevant: bidding competition, whereby bidders are forced to make offers *exceeding* the posttakeover share value. Given that private benefits are not pledgeable, offers exceeding the posttakeover share value must be funded in part out of the bidders' own funds. Consequently, the takeover outcome may depend not only on bidders' willingness to pay, that is, their valuations of the target, but also on their *ability* to pay.

If bidders are arbitrarily wealthy, the takeover outcome depends exclusively on their willingness to pay. This is the situation analyzed in much of the theory of takeovers. As the most efficient bidder, that is, the one who creates the most value, has the highest valuation of the target, he can always outbid less efficient rivals. Thus, absent financial constraints, the takeover outcome is always efficient.

By contrast, if bidders are financially constrained, the takeover outcome may be inefficient. To illustrate, suppose there are two bidders, bidder 1 and bidder 2. The target value is normalized to zero. If bidder 1 gains control, the target value increases to 100, while if bidder 2 gains control, it increases only to 90. Thus, bidder 1 is more efficient. Suppose next that, once in control, both bidders can divert the same fraction of firm value, say 30%, as private benefits. Hence, if bidder 1 gains control, the posttakeover share value is 70 and the bidder's private benefits are 30. Similarly, if bidder 2 gains control, the posttakeover share value is 63 and the bidder's private benefits are 27. Thus, not only is bidder 1 more efficient, but he can also raise more outside funds: bidder 1's outside funding capacity is 70 while bidder 2's outside funding capacity is only 63. (Recall that private benefits are not pledgeable.) And yet, bidder 2 may win

the takeover contest. To see this, assume that bidder 1 has no private wealth while bidder 2 has private wealth of 8. In this case, bidder 1 is able to pay 70 for the target but bidder 2 is able to pay 71: he can raise 63 from outside investors and use 8 of his own wealth. Consequently, bidder 2 can outbid his more efficient rival, bidder 1, and win the takeover contest.⁴

Accordingly, if bidders are financially constrained, the takeover outcome may depend not only on their ability to create value but also on their private wealth. In particular, if the less efficient bidder, that is, the one who creates less value, is wealthier, the takeover outcome may be inefficient. In this case, stronger legal investor protection may improve efficiency. To continue with the above example, suppose that legal investor protection is now such that bidders can divert only 10% of firm value (vs. 30% before). As a consequence, bidder 1's outside funding capacity is now 90 while bidder 2's outside funding capacity is only 81. If the bidders' private wealth is the same as before, this implies that bidder 1 can now pay 90 for the target while bidder 2 can only pay $81 + 8 = 89$. Thus, bidder 1 can now outbid his less efficient rival, bidder 2.

We explore a number of implications of this argument, both normative and positive. First, we examine the role of financing frictions, such as margin requirements ("haircuts") and shadow costs of internal funds. As we show, while margin requirements impair the efficiency of the takeover outcome, shadow costs of internal funds improve it. Intuitively, margin requirements reduce a bidder's capacity to raise outside funds, which hurts more efficient (but less wealthy) bidders relatively more. In contrast, shadow costs of internal funds hurt less efficient (but wealthy) bidders relatively more by making it more costly for them to draw on their internal funds. Our model predicts that the positive effect of legal investor protection on the takeover outcome is weaker when margin requirements are high and internal funds command a high shadow cost.

Our model also sheds new light on the "one share–one vote" rule, which stipulates that all shares have equal voting rights. The leading argument in support of this rule is that it minimizes the likelihood that more efficient bidders with low private benefits are outbid by less efficient rivals with high private benefits (Grossman and Hart (1988), Harris and Raviv (1988)). Naturally, this argument does not apply in our model, as the most efficient bidder is also the one with the highest private benefits. Nonetheless, a one share–one vote rule is optimal in our model, because it minimizes the likelihood that more efficient but less wealthy bidders are outbid by less efficient but wealthier rivals. Our model predicts that deviations from one share–one vote are more detrimental to efficiency when legal investor protection is weak.

We also analyze situations in which a bidder seeks to acquire a majority of the target shares from an incumbent blockholder. Effectively, the incumbent is like a rival bidder who is arbitrarily wealthy: he can always afford the controlling

⁴ Bidder 1 is *willing* to pay up to 100 for the target while bidder 2 is *willing* to pay up to 90. Hence, if the bidders were financially unconstrained, bidder 1 would always win the takeover contest.

block by simply refusing to sell it. Our model predicts that efficient sales of control are more likely to succeed when legal investor protection is strong and the incumbent's controlling block is large. In a second step, we endogenize the (optimal) size of the incumbent's controlling block and find it to be larger when legal investor protection is weak. This latter result is consistent with empirical evidence by La Porta et al. (1998) and La Porta, Lopez-de-Silanes, and Shleifer (1999) showing that ownership is more concentrated in countries with weaker legal investor protection.

We next examine issues related to cross-border M&A. We show that, if bidders from different countries compete for a target, those from countries with stronger legal investor protection enjoy a strategic advantage. Our model predicts that takeover premia in cross-border M&A deals are increasing in the quality of legal investor protection in the acquirer's country, consistent with empirical evidence by Bris and Cabolis (2008).

Finally, we show that firm-level governance, that is, institutions that limit private benefits extraction, can improve the efficiency of the takeover outcome. Indeed, if the cost of setting up such institutions is sufficiently low, legal investor protection and bidders' private wealth may be redundant. Our model predicts the strength of firm-level governance to be decreasing in its own cost, the bidder's wealth, and the strength of legal investor protection, and increasing in the value created by the bidder.

A recurrent theme in this paper is that legal investor protection helps efficient but less wealthy bidders. Almeida and Wolfenzon (2006, AW) obtain a related result. In their model, a penniless entrepreneur needs to fund a fixed setup cost to establish a firm. If the entrepreneur fails, the firm is set up by a wealthy but less efficient family. Stronger legal investor protection increases the entrepreneur's outside funding capacity and, since the funding needs are fixed, relaxes his budget constraint. This effect of legal investor protection also holds true in our model, *but only holding funding needs constant*. However, central to our analysis is the feature that not only funding capacity but also funding needs are endogenous to legal investor protection, that is, legal investor protection affects both sides of the budget constraint. This is true both in the single-bidder case (because the bid price increases in lockstep with the bidder's pledgeable income) and in the competition model (because the rival's maximum bid depends on legal investor protection).

Essentially, AW's model is akin to our *single-bidder* model but assuming a fixed bid price. (In AW, the family does not really compete with the entrepreneur; it is merely second in line to pick the project if the entrepreneur fails to fund it.) Because of this difference, the two models yield opposite results. In AW's model, stronger legal investor protection improves efficiency by making it more likely that the (more efficient) entrepreneur can finance the project's fixed cost. In contrast, in our single-bidder model, stronger legal investor protection does not improve efficiency, as the bid price—the equivalent of the project's cost—adjusts in lockstep. Indeed, stronger legal investor protection makes efficient takeovers *less likely* in our single-bidder model by reducing the bidder's profit from the takeover.

The paper proceeds as follows. Section I lays out the basic model. Section II analyzes the single-bidder case while Section III examines that of “effective” bidding competition. Section IV considers financing frictions, such as margin requirements and shadow costs of internal funds, as well as the role of asset tangibility. Section V examines the optimal security-voting structure, sales of controlling blocks, and cross-border M&A. Section VI studies the interplay between legal investor protection and firm-level governance. Section VII concludes. All remaining proofs are in Appendix A.

I. The Model

We consider a model of takeovers in which potential acquirers are financially constrained. Suppose a firm (“target”) faces a potential acquirer (“bidder”). The target has a measure one continuum of shares that are dispersed among many small shareholders. (Section V.B considers the case in which the target has a controlling shareholder.) All shares have equal voting rights. (Section V.A considers departures from one share–one vote.) Shareholders are homogeneous, everybody is risk neutral, and there is no discounting.

The target value is normalized to zero. If the bidder gains control of the target, its value increases to $v > 0$. To gain control, the bidder must make a tender offer to the target shareholders that attracts at least a majority of the shares. (The bidder has no initial stake in the target.) Target shareholders are atomistic in the sense that no individual shareholder perceives himself as pivotal for the outcome of the tender offer. Tender offers are conditional upon acquiring at least a majority of the shares and unrestricted in the sense that the bidder must acquire any and all shares beyond this threshold.⁵ If the tender offer is successful, the bidder incurs a monetary execution cost $c > 0$ that cannot be imposed on either the target or its shareholders—that is, unless the target is fully owned by the bidder, in which case the assumption is irrelevant.⁶

Even if a control transfer is efficient ($v > c$), it may not take place. As Bradley (1980) and Grossman and Hart (1980) show, if no individual target shareholder perceives himself as pivotal for the outcome of the tender offer, efficient takeovers will not materialize unless the bidder can extract private benefits of control. Accordingly, we assume that, after gaining control, the bidder can divert a fraction $(1 - \phi)$ of the target value as private benefits, where $\phi \in [\bar{\phi}, 1]$. For simplicity, we assume that private benefits extraction involves no dead-weight loss. Thus, the bidder’s private benefits are $(1 - \phi)v$ while the security benefits accruing to all shareholders are ϕv . Importantly, the extraction of private benefits cannot be contracted upon. This implies that the bidder cannot commit to a given level of private benefits, nor can he transfer or pledge these

⁵ Introducing restricted bids into our framework would affect neither the takeover outcome nor the payoffs to the bidder and the target shareholders.

⁶ With multiple bidders, it is important that the execution cost is incurred only by the winning bidder. Otherwise, at least when the bidding outcome is deterministic, there would never be any bidding competition because the losing bidder would not break even.

benefits to third parties (e.g., investors).⁷ Instead, the legal environment—captured by the parameter $\bar{\phi}$ —effectively limits diversion, with larger values of $\bar{\phi}$ corresponding to stronger legal investor protection.

Our assumption that private benefits are not pledgeable while security benefits are fully pledgeable simplifies the exposition but is stronger than necessary. Indeed, it suffices to assume that private benefits are less pledgeable than security benefits. This is plausible, especially if private benefits come partly in the form of consumption (e.g., perks) or are obtained in semilegal ways.

In practice, a controlling shareholder can extract private benefits at the expense of other investors in various ways. For instance, he can sell target assets or output below their market value to another company he owns. Alternatively, he can pay himself an artificially high salary or consume perks while declaring them business expenses. Johnson et al. (2000) describe how, even in countries like France, Belgium, and Italy, controlling shareholders can extract private benefits by transferring company resources to themselves (“tunneling”). Bertrand, Mehta, and Mullainathan (2002), Bae, Kang, and Kim (2002), Atanasov (2005), and Mironov (2013) provide further examples of tunneling from India, Korea, Bulgaria, and Russia, respectively.⁸

To study the financing of takeovers, we assume that the bidder has internal funds $A \geq 0$. In addition, the bidder can raise outside funds $F \geq 0$ from competitive investors. Since private benefits are not pledgeable, the bidder’s outside funding capacity is limited by the value of his security benefits. We impose no restriction on the types of financial claims that the bidder can issue against these security benefits.

The sequence of events is as follows:

In stage 1, the bidder decides whether to bid for the target. If he decides to bid, he can raise outside funds F in addition to his internal funds and make a take-it-or-leave-it, conditional, unrestricted cash tender offer with bid price b .

In stage 2, the target shareholders simultaneously and noncooperatively decide whether to tender their shares. The fraction of tendered shares is denoted by β . If $\beta < 0.5$, the takeover fails. Conversely, if $\beta \geq 0.5$, the takeover succeeds, tendering shareholders receive a cash payment equal to the bid price, and the bidder incurs the execution cost, c .

In stage 3, if the bidder gains control of the target, he diverts a fraction $(1 - \phi)$ of its value as private benefits subject to the constraint $\phi \geq \bar{\phi}$ imposed by the law.

To select among multiple equilibria, we apply the Pareto-dominance criterion, which selects the equilibrium outcome with the highest payoff for the

⁷ Our assumption that private benefits are not pledgeable rules out the possibility that the bidder can directly pledge target assets as collateral even if he does not fully own the target, as discussed in Mueller and Panunzi (2004). Such arrangements, which rely on second-step mergers between the target and a shell company owned by the bidder, are not available in all countries. Even in the United States, their role has been diminished due to the widespread adoption of (anti-)business combination laws.

⁸ Barclay and Holderness (1989), Nenova (2003), and Dyck and Zingales (2004) empirically document the value of private benefits of control.

target shareholders (e.g., Grossman and Hart (1980), Burkart, Gromb, and Panunzi (1998), Mueller and Panunzi (2004)). Among other things, this implies that our focus on value-increasing takeovers is without loss of generality. Indeed, any equilibrium of the tendering subgame in which a value-decreasing takeover succeeds is dominated by an equilibrium in which the takeover fails, where the latter equilibrium always exists.⁹ Thus, Pareto dominance rules out what is by all means an implausible scenario, namely, that target shareholders would tender at a bid price below the status quo value.¹⁰

The model is solved by backward induction. We first consider the bidder's diversion decision followed by the target shareholders' tendering decision and the bidder's offer and financing decisions. In general, a successful bid must win the target shareholders' approval and match any competing offer(s). We examine both the case in which shareholder approval is the binding constraint ("single-bidder case") and the case in which outbidding of rivals is the binding constraint ("bidding competition").

II. Single-Bidder Case

The single-bidder assumption does not literally rule out the possibility of other bidders being interested in the target. It merely presumes that competition is "ineffective," in the sense that no rival can create nearly as much value as the bidder under consideration. By implication, shareholder approval is then the binding constraint for a successful takeover.

Consider first stage 3, where the bidder must decide how much value to divert as private benefits. If the bidder gains control, he chooses ϕ to maximize

$$\beta\phi v - F(\beta\phi v) + (1 - \phi)v, \quad (1)$$

where $\beta\phi v$ is the value of the security benefits associated with the bidder's equity stake, $F(\beta\phi v)$ is the value of the outside claims issued against these security benefits, and $(1 - \phi)v$ is the value of the bidder's private benefits. Given that the extraction of private benefits involves no deadweight loss, maximum diversion is always optimal: $\phi = \bar{\phi}$.¹¹ Thus, legal investor protection imposes a

⁹ There is always a Nash equilibrium, in fact, a continuum of Nash equilibria, in which the takeover fails. If it is anticipated that a majority of the target shareholders do not tender, any individual shareholder is indifferent between tendering and not tendering, implying that failure can always be supported as an equilibrium outcome. Note that, while unconditional offers may avoid problems of multiple equilibria, they suffer from problems of nonexistence of equilibrium (e.g., Bagnoli and Lipman (1988)).

¹⁰ Grossman and Hart (1980, p. 47) also argue that bids below the status quo value are implausible, for exactly the same reason, namely, because they fail whenever they are expected to fail. Naturally, a value-decreasing takeover ($v < 0$) may succeed if the bidder were to make an offer above the status quo value: $b > 0$. However, making such an offer would violate the bidder's participation constraint.

¹¹ Maximum diversion is *strictly* optimal if either $\beta < 1$ or $F(\phi v) > \bar{\phi}v$ for some $\phi > \bar{\phi}$ on a set of positive measure. In contrast, the bidder is indifferent between diverting and not diverting if both

binding constraint on diversion, and the value of the security benefits increases with the quality of legal investor protection.

Consider next stage 2, where the target shareholders must decide whether to tender their shares. Being atomistic, target shareholders tender only if the bid price equals or exceeds the posttakeover value of the security benefits (Bradley (1980), Grossman and Hart (1980)). Thus, a successful tender offer must satisfy the free-rider condition

$$b \geq \bar{\phi}v. \tag{2}$$

If this condition holds with equality, target shareholders are indifferent between tendering and not tendering. Without loss of generality, we break the indifference in favor of tendering.^{12,13} Thus, if the takeover succeeds, it succeeds with $\beta = 1$.

Finally, consider stage 1, where the bidder must choose the offer price b and secure financing for the takeover. A successful offer must satisfy the free-rider condition, (2), as well as two further conditions. First, the offer must satisfy the bidder’s participation constraint. Given that $\beta = 1$, this constraint can be written as

$$v - b - c \geq 0. \tag{3}$$

Note that the claims issued to outside investors and the funds provided by them do not appear in the participation constraint—they cancel out as investors are competitive.

Second, the offer must satisfy the bidder’s budget constraint. Given that $\beta = 1$, this constraint can be written as

$$A + \bar{\phi}v \geq b + c. \tag{4}$$

The left-hand side is the bidder’s total budget. Indeed, the bidder can pledge to outside investors no more than the value of his security benefits, implying that his outside funding capacity is limited to $\bar{\phi}v$. The right-hand side represents the bidder’s need for funds, which includes both the bid price and the execution cost, c .

Lowering the bid price increases the value of the bidder’s objective function, that is, the left-hand side of (3), while relaxing both his budget constraint and his participation constraint. Therefore, the optimal bid is such that the free-rider condition holds with equality:

$$b = \bar{\phi}v. \tag{5}$$

$\beta = 1$ and $F(\phi v) \leq \bar{\phi}v$ for all $\phi > \bar{\phi}$, that is, if the value of the outside claims is unaffected by his diversion decision.

¹² See Grossman and Hart (1980, pp. 45–47). A common motivation for this assumption is that the bidder could always break the indifference by raising the bid price infinitesimally.

¹³ A small (technical) caveat: we break the indifference in favor of tendering only if the outcome is such that the takeover succeeds. Hence, failure can still be supported as an equilibrium outcome.

Consequently, the bidder's budget constraint becomes

$$A \geq c, \quad (6)$$

while his participation constraint becomes

$$(1 - \bar{\phi})v \geq c. \quad (7)$$

Importantly, the bidder's budget constraint, (6), does not depend on the strength of legal investor protection. In the original budget constraint, (4), that is, before inserting the free-rider condition, the bidder's outside funding capacity increases with $\bar{\phi}$. Indeed, stronger legal investor protection limits the bidder's ability to extract private benefits at the expense of other investors. This increases his pledgeable income, thereby increasing his outside funding capacity. However, once the free-rider condition is accounted for, the increased outside funding capacity does not relax the bidder's budget constraint, because the bid price, and thus the bidder's need for funds, increases in lockstep: $b = \bar{\phi}v$. Ultimately, the budget constraint is thus independent of legal investor protection. Also, with all pledgeable value being captured by the target shareholders, none of this value can be used to raise funds to cover the execution cost, c . Accordingly, that cost must be funded entirely out of the bidder's internal funds: $A \geq c$.

The more familiar participation constraint, (7), reflects the fact that free-riding by the target shareholders limits the bidder's profits to his private benefits net of the execution cost. Stronger legal investor protection reduces the bidder's private benefits, thereby tightening his participation constraint.

Combining (6) and (7), we obtain the following result:

LEMMA 1: *The bidder takes over the target if and only if*

$$\min\{(1 - \bar{\phi})v, A\} \geq c. \quad (8)$$

To summarize, legal investor protection affects the takeover outcome in two ways. On the one hand, stronger legal investor protection reduces the bidder's profit, making efficient takeovers less likely. On the other hand, stronger legal investor protection increases the bidder's pledgeable income and therefore his outside funding capacity. The latter effect is immaterial, however, as the bid price, and thus the bidder's need for funds, increases in lockstep with his pledgeable income.

Let us briefly contrast our single-bidder model with the standard corporate finance model of investment (e.g., Tirole (2006), chapters 3 and 4). In the standard model, increasing the entrepreneur's pledgeable income relaxes his budget constraint and improves efficiency. In contrast, in our single-bidder model, increasing the bidder's pledgeable income does not relax his budget constraint, because the investment cost (i.e., the bid price) increases one-for-one with his pledgeable income due to free-riding by the target shareholders.

We conclude by examining the effect of legal investor protection on the likelihood that efficient takeovers succeed. In condition (8), the left-hand side

decreases with $\bar{\phi}$. Therefore, as the quality of legal investor protection improves, it becomes less likely that the bidder acquires the target.¹⁴

PROPOSITION 1: *Absent effective competition for the target, stronger legal investor protection makes it less likely that efficient takeovers succeed.*

Note that, conditional on the takeover succeeding, target shareholders benefit from stronger legal investor protection through a higher bid price. However, this has no implications for efficiency; it merely constitutes a wealth transfer from the bidder to the target shareholders. In contrast, the negative effect of legal investor protection on the bidder’s participation constraint has implications for efficiency, as it makes it less likely that efficient takeovers succeed in the first place.

III. Bidding Competition

As noted earlier, the single-bidder case does not literally rule out the possibility of multiple bidders competing for the target. It merely presumes that such competition is ineffective, in the sense that the binding constraint is shareholder approval—given by the free-rider condition (5)—and not outbidding of rivals. By contrast, effective bidding competition implies that the requirement to outbid rivals, rather than winning shareholder approval, determines the winning bid price.

We consider two potential bidders, bidder 1 and bidder 2, competing to gain control of the target. Bidder $i = 1, 2$ has internal funds A_i . If bidder i gains control, the target value increases to $v_i > 0$, where $v_1 > v_2$ without loss of generality. Regardless of which bidder gains control, his ability to extract private benefits is limited by the same legal environment, $\bar{\phi}$. (Section V.C examines the case in which bidders come from different legal environments.) The takeover process is the same as in the single-bidder case, except that both bidders make their offers simultaneously.

In stage 3, as before, the controlling bidder finds it optimal to divert a fraction $(1 - \bar{\phi})$ of the target value as private benefits. In stage 2, the target shareholders can be faced with up to two offers. The case of a single offer is as before. The case of two offers is as follows.

LEMMA 2: *In a Pareto-dominant equilibrium, the winning bid is the highest bid among those satisfying $b_i \geq \bar{\phi}v_i$, if any.*

In stage 1, the bidders must decide whether to bid for the target. If so, they make their offers simultaneously. Denote by \hat{b}_i the highest offer that bidder i is willing and able to make. That is, \hat{b}_i is the highest value of b_i satisfying the bidder’s participation constraint

$$v_i \geq b_i + c \tag{9}$$

¹⁴ Here and elsewhere, we say that an event is more likely if it occurs for a larger set of parameter values.

and budget constraint

$$A_i + \bar{\phi}v_i \geq b_i + c. \quad (10)$$

Accordingly, the highest offer that bidder i is willing and able to make is

$$\hat{b}_i = \bar{\phi}v_i + \min\{(1 - \bar{\phi})v_i, A_i\} - c. \quad (11)$$

The first term on the right-hand side represents the security benefits if bidder i gains control. The bidder is both willing and able to pay for these benefits as he can always pledge their value to outside investors. The third term is the execution cost, c , which reduces the bidder's willingness to pay for the target. Finally, the second term is the minimum of the bidder's private benefits and his internal funds, which increase his willingness and ability, respectively, to pay for the target.

LEMMA 3: *Bidder 1 wins the takeover contest if and only if*

$$\min\{(1 - \bar{\phi})v_1, A_1\} \geq c \quad (12)$$

and

$$A_1 \geq \min\{(1 - \bar{\phi})v_2, A_2\} - \bar{\phi}(v_1 - v_2). \quad (13)$$

Lemma 3 lays out two conditions for bidder 1 to win the takeover contest. The first condition, (12), states that bidder 1 must be willing to incur and able to fund the execution cost. This condition is the same as in the single-bidder case. It is independent of bidder 2's presence or characteristics. If this condition does not hold, there is either no bidding competition or no bidding at all.¹⁵ Consequently, to allow for bidding competition, we assume that c is small enough for condition (12) to hold.

ASSUMPTION 1: $\min\{(1 - \bar{\phi})v_1, A_1\} \geq c$.

The second condition, (13), arises solely due to bidding competition. It determines under what conditions bidder 1's maximum offer, \hat{b}_1 , exceeds bidder 2's maximum offer, \hat{b}_2 . According to condition (13), bidder 1's internal funds, A_1 , must exceed some minimum threshold. Accordingly, the right-hand side of (13) captures the extent to which bidding competition tightens bidder 1's budget constraint. Importantly, the right-hand side decreases with $\bar{\phi}$. Hence, as the quality of legal investor protection improves, competition has less of a tightening effect on bidder 1's budget, making it more likely that he can outbid his less efficient rival, bidder 2.

PROPOSITION 2: *Under effective competition for the target, stronger legal investor protection makes it more likely that efficient takeovers succeed.*

¹⁵ If $\min\{(1 - \bar{\phi})v_1, A_1\} = (1 - \bar{\phi})v_1 < c$, both bidders' participation constraints are violated as $\min\{(1 - \bar{\phi})v_2, A_2\} \leq (1 - \bar{\phi})v_2 < (1 - \bar{\phi})v_1$. In that case, there is no bidding at all.

When the more efficient bidder is wealthier ($A_1 \geq A_2$), condition (13) always holds, that is, irrespective of the quality of legal investor protection. Indeed, bidder 1 not only has a higher valuation of the target, but he also has a larger budget: he has both more internal funds ($A_1 \geq A_2$) and higher outside funding capacity ($\bar{\phi}v_1 > \bar{\phi}v_2$). Thus, while bidder 2's presence may very well force bidder 1 to raise his bid, it will never exhaust bidder 1's budget constraint. By implication, bidder 1 always wins the takeover contest, and the quality of legal investor protection is irrelevant for the takeover outcome.

Suppose now instead that the less efficient bidder is wealthier ($A_1 < A_2$). When legal investor protection is weak, the outcome is now more likely to be inefficient. To illustrate, consider the extreme case in which investors enjoy no legal protection at all ($\bar{\phi} = 0$). In that case, the two bidders have no outside funding capacity and must rely entirely on their own funds to finance their bids. While bidder 1 has a higher valuation of the target, his budget is tighter than bidder 2's (because $A_1 < A_2$), possibly so tight as to prevent him from making an offer exceeding bidder 2's. In that case, bidder 2 wins the takeover contest. As the quality of legal investor protection improves, both bidders can pledge a larger fraction of firm value to outside investors, which increases both their budgets. However, because bidder 1 can create more value, his budget increases more than bidder 2's, making it more likely that he can outbid his less efficient rival. Indeed, in the budget constraint (10), the left-hand side increases with $\bar{\phi}$ at a rate of v_i . Given that $v_1 > v_2$, an increase in $\bar{\phi}$ therefore increases bidder 1's budget more than it increases bidder 2's budget.

Formally, it follows from condition (13) that, if $A_1 \geq \min\{v_2, A_2\}$, the takeover outcome is always efficient, that is, regardless of the quality of legal investor protection. In all other cases, there exists a critical value $\bar{\phi}' > 0$ such that the takeover outcome is efficient if and only if $\bar{\phi} \geq \bar{\phi}'$.

We next examine whether, conditional on the takeover succeeding, target shareholders benefit from stronger legal investor protection. To win the takeover contest, a bidder must not only outbid his rival(s), but his offer must also satisfy the free-rider condition. Accordingly, the winning bid is given by $b_i^* = \max\{\hat{b}_j, \bar{\phi}v_i\}$ for $j \neq i$. As the losing bidder's maximum bid, \hat{b}_j , is (weakly) increasing in $\bar{\phi}$, this implies that the winning bid is also (weakly) increasing in $\bar{\phi}$. Intuitively, stronger legal investor protection affects the bid price through two channels. First, it increases the value of the security benefits regardless of the winning bidder's identity ($\bar{\phi}v_i$ increases with $\bar{\phi}$), forcing each bidder to raise his bid. Second, it increases both bidders' outside funding capacity, allowing them to compete more fiercely for the target's shares (\hat{b}_i increases weakly with $\bar{\phi}$). For both reasons, stronger legal investor protection raises the winning bid price. Consistent with this result, Rossi and Volpin (2004) find that takeover premia are higher in countries with stronger legal investor protection.

Why is the effect of legal investor protection in the competition model different from that in the single-bidder case? After all, in both cases, stronger legal investor protection improves bidders' outside funding capacity; bidder i 's

outside funding capacity, $\bar{\phi}v_i$, increases with $\bar{\phi}$ at a rate of v_i (see conditions (4) and (10)). However, in the single-bidder case, the bid price, and hence the bidder's *need* for funds, increases in lockstep (i.e., at the same rate) due to the binding free-rider condition, (5). Consequently, the bidder's budget constraint is not relaxed. By contrast, in the competition model, the winning bid b_i^* is determined by the losing bidder's maximum offer \hat{b}_j (i.e., if competition is effective). Accordingly, bidder 1's outside funding capacity increases with $\bar{\phi}$ at a rate of v_1 , while his need for funds—in order to make a (winning) bid equal to bidder 2's maximum offer—increases only at a rate of v_2 (see condition (11)).¹⁶ This relaxes bidder 1's budget constraint and makes it more likely that he wins the takeover contest, which is efficient. The opposite is true for bidder 2, whose need for funds increases at a rate of v_1 while his outside funding capacity increases only at a rate of v_2 . This tightens bidder 2's budget constraint and makes it less likely that he wins.

IV. Financing Frictions

The main contribution of this paper is to incorporate financing constraints into a standard takeover model. Doing so puts the focus on the bidders' budget constraints, with the implication that they may frustrate efficient takeovers. This section studies financing frictions that may affect bidders' budgets and therefore the efficiency of the takeover outcome. Section IV.A considers margin requirements that limit bidders' outside funding capacity. Section IV.B analyzes shadow costs of internal funds. Section IV.C explores the role of asset tangibility.

A. Margin Requirements

Margin requirements are common in lending. For instance, when lending cash to investors for the purpose of buying securities, brokers typically require that investors put up equity of their own. Reasons for margin requirements are moral hazard and asymmetric information on the part of the borrower, which can be mitigated if the borrower puts up some equity of his own, and the aversion of lenders to possess collateral, which can be mitigated if the asset comes with an equity buffer that prevents it from going "under water" too quickly. Consistent with investors' reluctance to lend an amount equal to the full asset value, we assume that they provide funds only up to $(1 - \pi)\bar{\phi}v$, where $\bar{\phi}v$ is the pledgeable asset value, as before, and π is the fraction that the borrower needs to contribute out of his own pocket (i.e., the haircut).

¹⁶ The statement refers to the (interesting) case in which the bidders are financially constrained, so that $(1 - \bar{\phi})v_i > A_i$ in condition (11). By contrast, if $(1 - \bar{\phi})v_i \leq A_i$, each bidder can bid up to his full valuation, implying that the quality of legal investor protection is irrelevant.

A.1. Single-Bidder Case

The analysis of the single-bidder case is analogous to our basic model, with the exception that the bidder's budget constraint is replaced by

$$A + (1 - \pi)\bar{\phi}v \geq b + c. \tag{14}$$

Inserting the binding free-rider condition $b = \bar{\phi}v$ into (14), we obtain

$$A \geq \pi\bar{\phi}v + c. \tag{15}$$

Note that margin requirements affect the bidder's budget constraint but not the free-rider condition, as they do not affect the fundamental value of the target if taken over by the bidder. Consequently, after inserting the binding free-rider condition, the budget constraint does not collapse into the familiar constraint $A \geq c$ from Section II (see condition (6)).

In conjunction with the bidder's participation constraint, (7), this yields the following result.

LEMMA 4: *The bidder takes over the target if and only if*

$$\min\{(1 - \bar{\phi})v, A - \pi\bar{\phi}v\} \geq c. \tag{16}$$

By inspection, stronger legal investor protection impairs efficiency, for two reasons. First, as in our basic single-bidder model, stronger legal investor protection reduces the bidder's profits, thereby tightening his participation constraint. Second, and this effect is new, stronger legal investor protection tightens the bidder's budget constraint: while it raises his need for funds by $\bar{\phi}v$, through the binding free-rider condition $b = \bar{\phi}v$, it increases his outside funding capacity only by $(1 - \pi)\bar{\phi}v$. As a consequence, the bidder faces a funding gap of $\pi\bar{\phi}v$, which he must cover out of his internal funds.

In condition (16), the left-hand side decreases with both $\bar{\phi}$ and π . Notably, the cross-derivative with respect to $\bar{\phi}$ and π is negative, implying that legal investor protection and margin requirements are complements: a higher value of one amplifies the negative effect of the other on the likelihood that the takeover succeeds.

In sum, when the bidder's outside funding capacity is impaired by margin requirements, stronger legal investor protection tightens both his participation constraint and his budget constraint. That said, the qualitative implication of Proposition 1, namely, that stronger legal investor protection makes efficient takeovers less likely, continues to hold.

A.2. Bidding Competition

The main change relative to the basic competition model is that bidder i 's budget constraint is now

$$A_i + (1 - \pi)\bar{\phi}v_i \geq b_i + c. \tag{17}$$

Together with the participation constraint, (9), this implies that the highest offer that bidder i is willing and able to make is

$$\widehat{b}_i = \bar{\phi}v_i + \min \{(1 - \bar{\phi})v_i, A_i - \pi\bar{\phi}v_i\} - c. \quad (18)$$

Given Assumption 1, we can again derive conditions under which bidder 1's maximum offer, \widehat{b}_1 , exceeds bidder 2's maximum offer, \widehat{b}_2 .

LEMMA 5: *Bidder 1 wins the takeover contest if and only if*

$$A_1 \geq \min \{(1 - \bar{\phi})v_2, A_2 - \pi\bar{\phi}v_2\} + \pi\bar{\phi}v_1 - \bar{\phi}(v_1 - v_2). \quad (19)$$

Note that the right-hand side is decreasing in $\bar{\phi}$ and increasing in π , while the cross-derivative of the right-hand side with respect to $\bar{\phi}$ and π is strictly positive.

PROPOSITION 3: *Under effective competition for the target, the takeover outcome is more likely to be efficient if legal investor protection is strong and margin requirements are low. Furthermore, the positive effect of legal investor protection is weaker when margin requirements are high while the negative effect of margin requirements is stronger when legal investor protection is strong.*

Intuitively, the right-hand side in (19) is increasing in π , because stronger margin requirements hurt bidder 1 relatively more than bidder 2 due to bidder 1's larger outside funding capacity. As for the cross-derivative, recall that stronger legal investor protection increases bidder 1's outside funding capacity more than bidder 2's. This can be easily seen from (17), where the difference $\Delta = (1 - \pi)\bar{\phi}(v_1 - v_2)$ is increasing in $\bar{\phi}$. That said, the rate of increase, $\frac{\partial \Delta}{\partial \bar{\phi}} > 0$, is decreasing in π , implying that the positive effect of legal investor protection—the increase in bidder 1's *relative* outside funding capacity—is weaker when margin requirements are high. Similarly, we have that $\frac{\partial \Delta}{\partial \pi} < 0$ is lower when $\bar{\phi}$ is high. While an increase in margin requirements always hurts bidder 1 relatively more, it hurts him (relatively) the most when the difference between his and bidder 2's outside funding capacity is largest, that is, when legal investor protection is strong.

Finally, the winning bid, $b_i^* = \max\{\widehat{b}_j, \bar{\phi}v_i\}$ for $j \neq i$, is (weakly) decreasing in π . Hence, our model predicts that takeover premia are lower when margin requirements are high.

B. Shadow Costs of Internal Funds

Thus far, we have assumed that bidders' internal funds are excess cash or liquid funds. However, in a world with financing frictions, firms presumably hold internal funds for a reason, for example, to smooth out operational risks or fund projects that otherwise cannot be funded. This, however, implies that internal funds ought to have a shadow value. Accordingly, we now assume that using $a \leq A$ units of internal funds entails a shadow cost of τa representing, for

example, the forgone return from alternative projects or the cost of liquidating assets that are less than fully liquid.

B.1. Single-Bidder Case

The analysis is analogous to our basic single-bidder model, except that the bidder's participation constraint is now

$$v - b - c - \tau a \geq 0. \tag{20}$$

Hence, using a units of internal funds lowers the bidder's payoff by τa . In contrast, the bidder's budget constraint depends only on his available internal funds, A , not on the amount actually used. Consequently, it is still given by (4) or, after inserting the binding free-rider condition, by (6).

Inserting the binding free-rider condition into (20) yields

$$(1 - \bar{\phi})v - \tau a \geq c. \tag{21}$$

Given that using internal funds involves a shadow cost, the bidder first exhausts his outside funding capacity. Hence, the amount of internal funds drawn on is $a = b + c - \bar{\phi}v$ or, after inserting the binding free-rider condition, $a = c$. As a result, the bidder's participation constraint becomes

$$(1 - \bar{\phi})v \geq (1 + \tau)c. \tag{22}$$

As one might have expected, an increase in the shadow cost of internal funds, τ , tightens the bidder's participation constraint.

Together with the bidder's budget constraint, (6), this yields the following result.

LEMMA 6: *The bidder takes over the target if and only if*

$$\min \left\{ \frac{(1 - \bar{\phi})v}{1 + \tau}, A \right\} \geq c. \tag{23}$$

As in our basic single-bidder model, legal investor protection has no effect on the bidder's budget constraint. However, it tightens his participation constraint, making efficient takeovers less likely.

Of particular interest is the fact that the cross-derivative of the left-hand side in (23) with respect to $\bar{\phi}$ and τ is positive. This has two implications. First, it implies that the negative effect of legal investor protection on efficiency is weaker when τ is high. Intuitively, while legal investor protection reduces the bidder's private benefits, it also improves the bidder's outside funding capacity, thereby reducing his need for internal funds, which is more valuable when internal funds command a high shadow value. Second, it implies that the negative effect of shadow costs of internal funds is weaker when legal investor protection is strong. Intuitively, stronger legal investor protection means that the bidder needs to use less internal funds, implying that a given increase in τ involves a smaller reduction in his payoff.

B.2. Bidding Competition

Analogous to the single-bidder case, the main change relative to our basic competition model is that bidder i 's participation constraint is now

$$v_i - b_i - c - \tau a_i \geq 0. \quad (24)$$

Given that bidder i fully exhausts his outside funding capacity before tapping into internal funds, the amount of internal funds drawn on is $a_i = b_i + c - \bar{\phi} v_i$. Hence, bidder i 's participation constraint becomes

$$\bar{\phi} v_i + \frac{(1 - \bar{\phi})v_i}{1 + \tau} - b_i - c \geq 0. \quad (25)$$

Together with his budget constraint, (10), this implies that the highest offer that bidder i is willing and able to make is

$$\hat{b}_i = \bar{\phi} v_i + \min \left\{ \frac{(1 - \bar{\phi})v_i}{1 + \tau}, A_i \right\} - c. \quad (26)$$

Again, we can determine the conditions under which bidder 1's maximum offer, \hat{b}_1 , exceeds bidder 2's maximum offer, \hat{b}_2 .

LEMMA 7: *Bidder 1 wins the takeover contest if and only if*

$$A_1 \geq \min \left\{ \frac{(1 - \bar{\phi})v_2}{1 + \tau}, A_2 \right\} - \bar{\phi}(v_1 - v_2). \quad (27)$$

Note that the right-hand side is decreasing in $\bar{\phi}$ and τ while the cross-derivative with respect to $\bar{\phi}$ and τ is strictly positive.

PROPOSITION 4: *Under effective competition for the target, the takeover outcome is more likely to be efficient if legal investor protection is strong and the shadow costs of internal funds are high. Furthermore, the positive effect of legal investor protection is weaker when internal funds command a high shadow cost while the positive effect of shadow costs of internal funds is weaker when legal investor protection is strong.*

In our analysis, the main inefficiency is that less efficient but wealthy bidders may win the takeover contest because (i) limited pledgeability constrains bidders' outside funding capacity and (ii) internal funds may allow them to overcome this funding gap and outbid more efficient but less wealthy rivals. Consequently, any financing friction making it more difficult or costly for bidders to raise *outside* funds, such as the margin requirements analyzed in the previous section, must reduce efficiency. Conversely, any financing friction making it more difficult, or costly, for bidders to draw on their *internal* funds must improve the efficiency of the takeover outcome.

Accordingly, high shadow costs of internal funds should improve efficiency: they make it less likely that wealthy but inefficient bidders find it profitable to

use their internal funds to outbid less wealthy but more efficient rivals. Intuitively, this positive effect is more pronounced when legal investor protection is weak, because this is precisely when internal funds matter the most and the associated inefficiency is greatest. It is also intuitive why the positive effect of legal investor protection is weaker when internal funds command a high shadow value: if internal funds are expensive, then inefficient but wealthy bidders are less likely to win in the first place, and institutions improving the relative outside funding capacity of more efficient bidders, such as legal investor protection, are relatively less important.

Finally, the winning bid, $b_i^* = \max\{\widehat{b}_j, \bar{\phi}v_i\}$ for $j \neq i$, is (weakly) decreasing in τ . Thus, while high shadow costs of internal funds improve efficiency, they are bad for target shareholders as they imply a lower bid premium.

C. Asset Tangibility

Some assets are more tangible than others, more difficult to divert, and their cash flows are more readily verifiable. In a world with financing frictions, such assets are desirable as they command a high outside funding capacity. From an empirical perspective, the role of asset tangibility for financing constraints is an important topic (e.g., Almeida and Campello (2007)). That being said, the forces through which asset tangibility and legal investor protection affect the takeover outcome are quite similar. Accordingly, we confine ourselves to a brief description of the results. The full analysis is provided in the Internet Appendix.¹⁷

To explore the effects of asset tangibility, we assume that a fraction ψ of the target value *cannot* be expropriated—irrespective of the quality of legal investor protection.¹⁸ In the single-bidder case, an increase in asset tangibility tightens the bidder's participation constraint but has no effect on his budget constraint. Thus, akin to the role of legal investor protection, an increase in asset tangibility makes it less likely that efficient takeovers succeed. By contrast, in the competition model, stronger legal investor protection and high asset tangibility both improve the efficiency of the takeover outcome. Importantly, the two are substitutes, meaning the effect of asset tangibility is weaker when legal investor protection is strong, and vice versa. Finally, the model predicts that takeover premia are higher when asset tangibility is high.

V. Miscellaneous Extensions

Taking into account the interaction between legal investor protection and financing constraints provides new insights into the optimal allocation of voting rights, the sale of controlling blocks, and the role of legal investor protection for cross-border M&A. For brevity, we focus here on the competition model, noting that the single-bidder case is straightforward to analyze. Given that the

¹⁷ The Internet Appendix may be found in the online version of this article.

¹⁸ Almeida and Campello (2007, p. 1430) argue that asset tangibility is "a proxy for pledgeability."

execution cost, c , matters only in the single-bidder case, we set $c = 0$ without loss of generality.

A. One Share–One Vote

This section studies the implications of departures from one share–one vote. Suppose the target has a dual-class share system: a fraction $\alpha \in (0, 1]$ of the shares have (equal) voting rights while the remaining shares are nonvoting. A one share–one vote structure corresponds to $\alpha = 1$.

In stage 3, as before, the controlling bidder finds it optimal to divert a fraction $(1 - \bar{\phi})$ of the target value as private benefits. In stage 2, target shareholders of different voting classes may face different bids, which they each must accept or reject. That is, we explicitly allow bidders to make different bids for voting and nonvoting shares. As it turns out, this problem can be simplified.

LEMMA 8: *Without loss of generality, we may assume that bidders make a bid only for voting shares.*

From the bidder's perspective, whether he acquires nonvoting shares is immaterial: they do not help him to gain control. Thus, the most he is willing to pay for these shares is their fundamental value, $\bar{\phi}v_i$.¹⁹ In contrast, as was shown in Section III, bidders may pay a higher price for voting shares to gain control of the target. Moreover, due to free-riding, nonvoting shareholders will tender only if the bid price is at least $\bar{\phi}v_i$. Accordingly, the only bid price at which a transaction may possibly occur is $\bar{\phi}v_i$. At this price, however, both parties are indifferent between trading and not trading. Thus, without loss of generality, we may assume that bidders do not make a bid for nonvoting shares.

The tendering decision is the same as in our basic model. Hence, by Lemma 2, voting shareholders tender to the highest bidder offering $b_i \geq \bar{\phi}v_i$, if any. In stage 1, the bidders must decide whether to bid for the target. Thus, we must again characterize the highest offer that bidder i is willing and able to make, $\bar{b}_i(\alpha)$, that is, the highest value of b_i satisfying the bidder's participation constraint

$$\alpha\bar{\phi}v_i + (1 - \bar{\phi})v_i \geq \alpha b_i. \quad (28)$$

and budget constraint

$$A_i + \alpha\bar{\phi}v_i \geq \alpha b_i. \quad (29)$$

In the participation constraint, (28), $\alpha\bar{\phi}v_i$ is the value of the security benefits associated with voting shares, $(1 - \bar{\phi})v_i$ is the bidder's private benefits, and αb_i is the total payout to voting shareholders. In the budget constraint, (29), the left-hand side represents the bidder's total budget, consisting of his internal

¹⁹ As is customary in the literature, we express bids in terms of a measure one of shares. Given that a fraction $(1 - \alpha)$ of the shares are nonvoting, this means the bidder is willing to pay up to $(1 - \alpha)\bar{\phi}v_i$ for all of the nonvoting shares.

funds, A_i , and his outside funding capacity, $\alpha\bar{\phi}v_i$, while the right-hand side reflects his need for funds.

Accordingly, the highest offer that bidder i is willing and able to make is

$$\widehat{b}_i = \bar{\phi}v_i + \frac{1}{\alpha} \cdot \min \{(1 - \bar{\phi})v_i, A_i\}. \tag{30}$$

This expression resembles (11), except that $c = 0$ and the second term is normalized by the fraction of voting shares, α . Indeed, when not all shares carry a vote, the bidder’s willingness and ability to pay are spread across fewer shares. This increases the maximum offer he is willing and able to make (for the voting shares). In particular, the bidder’s willingness to pay is higher, because he can now obtain the same private benefits by acquiring fewer shares. Similarly, his ability to pay is higher, because he can now use his private wealth for the acquisition of fewer shares.²⁰

LEMMA 9: *Bidder 1 wins the takeover contest if and only if*

$$A_1 \geq \min \{(1 - \bar{\phi})v_2, A_2\} - \alpha\bar{\phi}(v_1 - v_2). \tag{31}$$

By inspection, the right-hand side decreases with α . Thus, the likelihood that bidder 1 wins the takeover contest is highest under a one share–one vote structure.²¹

PROPOSITION 5: *One share–one vote is socially optimal.*

When the more efficient bidder is also wealthier ($A_1 \geq A_2$), condition (31) holds for any value of α . That is, the takeover outcome is always efficient, irrespective of the fraction of voting shares. The intuition is the same as in our basic model: not only does bidder 1 have a higher valuation of the target but he also has a larger budget. Hence, bidder 1 can always outbid his less efficient rival, bidder 2.

Suppose now instead that the less efficient bidder is wealthier ($A_1 < A_2$). If A_1 is sufficiently large, the takeover outcome is again efficient regardless of the fraction of voting shares. This situation, that is, when both bidders are financially unconstrained, is the situation analyzed in much of the theory of takeovers.

However, if A_1 is sufficiently small, the takeover outcome may be inefficient. Indeed, while bidder 1 has a higher willingness to pay for the target, bidder 2’s ability to pay may be higher due to his larger wealth. To illustrate, consider the (interesting) case in which bidders face binding financing constraints,

²⁰ Deviations from one share–one vote are equivalent to allowing restricted bids where the bidders compete for a fraction $\alpha \geq 0.5$ of the shares and the winner is the bidder with the highest bid.

²¹ In contrast, the security-voting structure (i.e., the value of α) is irrelevant in the single-bidder case, because the bid price must equal the posttakeover value of the security benefits.

$A_i \leq (1 - \bar{\phi})v_i$. By (30), this implies that the highest offer that bidder i is willing and able to make is

$$\hat{b}_i = \bar{\phi}v_i + \frac{A_i}{\alpha}. \quad (32)$$

Hence, even though bidder 2 generates lower security benefits ($\bar{\phi}v_2 < \bar{\phi}v_1$), his maximum offer may be higher than bidder 1's if A_2 is sufficiently larger than A_1 . Importantly, when α is small, a smaller wealth difference, $A_2 - A_1$, is needed for bidder 2 to outbid bidder 1. Intuitively, the effect of bidder wealth on the takeover outcome is larger when α is small, because a given amount of wealth can be spread across fewer voting shares.

More formally, it follows from condition (31) that, if $A_1 \geq \min\{(1 - \bar{\phi})v_2, A_2\}$, the takeover outcome is efficient for any value of α , that is, irrespective of the fraction of voting shares. By contrast, if $A_1 < \min\{(1 - \bar{\phi})v_2, A_2\} - \bar{\phi}(v_1 - v_2)$, the takeover outcome is inefficient for any value of α . In all intermediate cases, there exists a critical value

$$\hat{\alpha} = \frac{\min\{(1 - \bar{\phi})v_2, A_2\} - A_1}{\bar{\phi}(v_1 - v_2)} \quad (33)$$

such that the takeover outcome is efficient if and only if $\alpha \geq \hat{\alpha}$. By inspection, $\hat{\alpha}$ decreases with $\bar{\phi}$. Hence, departures from one share–one vote are more likely to lead to an inefficient takeover outcome when legal investor protection is weak. (Conversely, weak legal investor protection is more likely to lead to an inefficient takeover outcome when the fraction of voting shares, α , is small.)

COROLLARY 1: *Deviations from one share–one vote are more likely to lead to an inefficient takeover outcome when legal investor protection is weak.*

Our result must be contrasted with those in Grossman and Hart (1988, GH) and Harris and Raviv (1988, HR), who also find that one share–one vote is socially optimal. The economics behind their results, however, are fundamentally different. In GH and HR, departures from one share–one vote may allow bidders with low security benefits but high private benefits to win against bidders with high security benefits but low private benefits, even if the former are less efficient, that is, even if they generate lower *total* benefits. In our model, this is not possible because security and private benefits are positively aligned, that is, our model assumes that bidders can divert more value in absolute (i.e., dollar) terms from more valuable firms. In contrast, GH and HR both assume that bidders can divert more value in absolute terms from less valuable firms.

The converse is also true: the inefficiency in our model, which is minimized under a one share–one vote structure, does not arise in GH and HR. Recall that the main inefficiency in our model is not that less efficient bidders may have a higher *willingness* to pay, as in GH and HR, but rather that they may have a higher *ability* to pay. Hence, the sole reason why efficient takeovers may not materialize in our model is because bidders are financially constrained. In contrast, GH and HR both assume that bidders are arbitrarily wealthy, so financing constraints play no role.

B. Sales of Controlling Blocks

We next consider the case in which the target has a controlling shareholder (“incumbent”). The incumbent owns a fraction $\beta \geq 0.5$ of the target shares and generates firm value $v_0 \geq 0$, which is divided into security benefits $\bar{\phi}v_0$ and private benefits $(1 - \bar{\phi})v_0$. The target faces a (single) potential acquirer (“bidder”). If the bidder gains control, the target value increases to $v_1 > v_0$.

A transfer of control must be mutually beneficial, given that the incumbent can always block the transfer at will. Accordingly, a control transfer may occur only if the bidder is willing and able to compensate the incumbent for his controlling block. Consistent with the law and legal practice in the United States, we assume that minority shareholders enjoy no rights in this sale-of-control transaction. In particular, the bidder is under no obligation to extend his offer to minority shareholders. In fact, he is under no obligation to make them any offer at all. This rule, known as “market rule” (MR), is the prevailing rule in the United States. Given that it imposes no obligation on the acquirer, “the MR is probably best described as the absence of a rule, rather than a rule” (Schuster, 2013, p. 535).

Many other countries, including most European countries, use the “equal opportunity rule” (EOR), also known as “mandatory bid rule” (MBR), which requires that the bidder makes an offer to minority shareholders on the same terms as the offer to the controlling blockholder. At the end of this section, we offer a brief discussion of what might change if the bidder were subject to the EOR/MBR. A formal analysis is provided in the Internet Appendix.

In stage 3, as before, the bidder diverts a fraction $(1 - \bar{\phi})$ of the target value as private benefits. In stage 2, the incumbent and the minority shareholders may face different bids, which they each must accept or reject. Note the analogy to Section V.A. There, we assumed without loss of generality that bidders do not make a bid for nonvoting shares. Similarly, here, the bidder has nothing to gain from acquiring minority shares: they do not help him gain control, and the only price at which a transaction may occur is at their fundamental value, $\bar{\phi}v_1$, making everybody indifferent between trading and not trading. Analogous to Lemma 8, we can thus assume without loss of generality that the bidder does not make a bid for minority shares.

We must again characterize the highest offer that the bidder is willing and able to make, $\hat{b}_1(\beta)$, that is, the highest value of b_1 satisfying his participation constraint

$$\beta\bar{\phi}v_1 + (1 - \bar{\phi})v_1 \geq \beta b_1 \tag{34}$$

and budget constraint

$$A_1 + \beta\bar{\phi}v_1 \geq \beta b_1. \tag{35}$$

Conditions (34) and (35) are similar to (28) and (29), except that α is replaced with β . Accordingly, the highest offer that the bidder is willing and able to make is

$$\widehat{b}_1 = \bar{\phi}v_1 + \frac{1}{\beta} \cdot \min \{ (1 - \bar{\phi})v_1, A_1 \}, \quad (36)$$

while the incumbent's valuation of the controlling block is

$$\beta b_0 = \beta \bar{\phi}v_0 + (1 - \bar{\phi})v_0. \quad (37)$$

For a sale-of-control transaction to occur, the bidder's maximum offer for the controlling block, $\widehat{\beta b}_1$, must equal or exceed the incumbent's valuation of the block, βb_0 .²² Otherwise, there are no gains from trade.²³

LEMMA 10: *The bidder gains control of the target if and only if*

$$A_1 \geq (1 - \bar{\phi})v_0 - \beta \bar{\phi}(v_1 - v_0). \quad (38)$$

Condition (38) is similar to condition (31). The latter condition reflects the requirement that bidder 1's maximum offer for the block of voting shares, $\alpha \widehat{b}_1$, must exceed bidder 2's maximum offer, $\alpha \widehat{b}_2$. Similarly, condition (38) states that the bidder's maximum offer for the controlling block, $\beta \widehat{b}_1$, must exceed the incumbent's valuation, βb_0 . The main difference is that the incumbent's wealth does not enter in condition (38). As the incumbent already owns the controlling block, his ability to pay is irrelevant. In a way, the incumbent is like a rival bidder who is arbitrarily wealthy.

By inspection, the right-hand side of (38) decreases with β . Thus, the likelihood that the sale of control takes place increases with the size of the controlling block.

PROPOSITION 6: *Efficient sales of control are more likely to succeed when the controlling block is large (as a fraction of the total equity value).*

Recall that the incumbent's wealth plays no role: he can always afford the controlling block by simply refusing to sell it. Accordingly, whether the sale of control takes place depends solely on the bidder's wealth. If A_1 is sufficiently large, the sale of control always takes place, irrespective of the size of the controlling block. Thus, absent financial constraints, the takeover outcome is always efficient.

In contrast, if the bidder is financially constrained, the sale of control may not take place. More precisely, for the sale of control to succeed, the bidder must compensate the incumbent for his security benefits, $\beta \bar{\phi}v_0$, and his private benefits, $(1 - \bar{\phi})v_0$. To do so, the bidder can use his internal funds, A_1 , and his outside

²² Recall that we express bids in terms of a measure one of shares. Thus, if \widehat{b}_1 is the highest offer that the bidder is willing and able to make, his maximum offer for the controlling block is $\beta \widehat{b}_1$.

²³ The sale will occur at some price $\beta b \in [\beta b_0, \beta \widehat{b}_1]$ depending on the incumbent's and bidder's relative bargaining powers. For our purposes, the value of b is not of interest, as it does not affect efficiency.

funds, $\beta\bar{\phi}v_1$. Clearly, if $A_1 \geq (1 - \bar{\phi})v_0$, the sale of control always takes place. In contrast, if $A_1 < (1 - \bar{\phi})v_0$, the bidder is unable to pay for all of the incumbent's private benefits out of his internal funds and must consequently tap his outside funds, $\beta\bar{\phi}v_1$. However, since the bidder must also pay for the incumbent's security benefits, $\beta\bar{\phi}v_0$, his disposable outside funds are only $\beta(\bar{\phi}v_1 - \bar{\phi}v_0)$. If this is large enough to cover the funding gap of $(1 - \bar{\phi})v_0 - A_1$, the sale of control will take place. Otherwise, it will fail. Importantly, the bidder's disposable outside funds are increasing in β , which explains Proposition 6.

Formally, it follows from condition (38) that, if $A_1 \geq (1 - \bar{\phi})v_0 - \frac{\bar{\phi}}{2}(v_1 - v_0)$, the sale of control always takes place—irrespective of the size of the controlling block. By contrast, if $A_1 < (1 - \bar{\phi})v_0 - \bar{\phi}(v_1 - v_0)$, the sale of control never takes place. In all intermediate cases, there exists a critical value $\hat{\beta} \geq 0.5$ given by

$$\hat{\beta} = \frac{(1 - \bar{\phi})v_0 - A_1}{\bar{\phi}(v_1 - v_0)} \tag{39}$$

such that the sale of control takes place if and only if $\beta \geq \hat{\beta}$. By inspection, $\hat{\beta}$ decreases with $\bar{\phi}$. Thus, efficient sales of control are more likely to occur when legal investor protection is strong.

COROLLARY 2: *Stronger legal investor protection makes it more likely that efficient sales of control take place.*

Bebchuk (1994) also finds that efficient sales of control may not take place, albeit for a different reason. In his model, an incumbent with low security benefits but high private benefits may not sell his controlling block to a potential acquirer with high security benefits but low private benefits, even if the sale of control is efficient. In our model, this possibility cannot arise, as security and private benefits are positively aligned. Instead, efficient sales of control may fail in our model because bidders are financially constrained. In contrast, in Bebchuk's model, bidders are arbitrarily wealthy, so financing constraints play no role.

Thus far, we have (implicitly) assumed that the bidder makes an offer for the *entire* controlling block. We should point out that none of our results depend on this assumption. Given that the likelihood of an efficient sale of control depends on the size of the controlling block, this may seem surprising. However, it is easy to show that condition (38)—the central condition characterizing when the bidder gains control of the target—remains *unchanged* if we allow the bidder to make a (restricted) offer for only a fraction of the controlling block.

To see this, suppose the bidder makes a bid $b_{1,\kappa}$ for a fraction $\kappa < 1$ of the controlling block, where $\kappa\beta \geq 0.5$ ensures that he acquires enough shares to gain control. We must again characterize the highest value of $b_{1,\kappa}$ satisfying the bidder's participation constraint

$$\kappa\beta\bar{\phi}v_1 + (1 - \bar{\phi})v_1 \geq \kappa\beta b_{1,\kappa} \tag{40}$$

and budget constraint

$$A_1 + \kappa\beta\bar{\phi}v_1 \geq \kappa\beta b_{1,\kappa}. \quad (41)$$

Hence, the highest offer that the bidder is willing and able to make is

$$\widehat{b}_{1,\kappa} = \bar{\phi}v_1 + \frac{1}{\kappa\beta} \cdot \min\{(1 - \bar{\phi})v_1, A_1\}. \quad (42)$$

Comparing (42) with (36) shows that allowing the bidder to make a restricted bid raises his maximum offer: $\widehat{b}_{1,\kappa} > \widehat{b}_1$. Intuitively, the bidder is both willing and able to pay a higher price as he can spread his private benefits and wealth, respectively, over fewer shares. However, this offer is now only for a fraction κ of the incumbent's shares. The remaining fraction, $1 - \kappa$, is valued at the posttakeover share value $\bar{\phi}v_1 < \widehat{b}_1$, with the implication that the incumbent's total payoff remains *exactly* the same as before:

$$\kappa\beta\widehat{b}_{1,\kappa} + (1 - \kappa)\beta\bar{\phi}v_1 = \beta\widehat{b}_1. \quad (43)$$

Intuitively, the incumbent's total payoff, that is, the left-hand side in (43), can be decomposed into two parts: the security benefits associated with his controlling block, $\beta\bar{\phi}v_1$, and the control premium paid by the bidder. The security benefits are evidently independent of κ . But so is the control premium. By (42), the control premium is equal to $\kappa\beta \times \frac{1}{\kappa\beta} \cdot \min\{(1 - \bar{\phi})v_1, A_1\}$, which depends only on the bidder's private benefits, $(1 - \bar{\phi})v_1$, and wealth, A_1 .²⁴

Having established that the incumbent's payoff is independent of how many shares he sells, as long as enough are sold to allow the bidder to gain control, the rest of the argument is straightforward. In particular, as the incumbent's payoff remains unchanged, the central condition in Lemma 10 describing when the sale of control succeeds, (38), is also unchanged.²⁵ Naturally, this implies that all results building on Lemma 10, such as Proposition 6 and Corollary 2, also remain unchanged.

Returning to our main analysis, we now endogenize the size of the incumbent's controlling block. Suppose the incumbent is initially the firm's sole owner. In the spirit of Zingales (1995), he can retain a controlling block, $\beta \geq 0.5$, and sell the remaining shares, $1 - \beta$, to dispersed investors. At some future date, the firm is approached by a potential bidder, as described, and a control transfer may take place. As in Zingales's analysis, everybody has rational expectations about this future control transfer. For simplicity, we assume that the bidder has full bargaining power vis-à-vis the incumbent, though all of our qualitative results remain valid as long as the bidder has *some* bargaining power.

²⁴ Recall that bids are expressed in terms of a measure one of shares. Thus, to obtain the control premium (in dollars), one must multiply $\frac{1}{\kappa\beta} \cdot \min\{(1 - \bar{\phi})v_1, A_1\}$ in (42) with the size of the block that is being traded, $\kappa\beta$.

²⁵ More precisely, the sale of control takes place if and only if

$$\kappa\beta\widehat{b}_{1,\kappa} + (1 - \kappa)\beta\bar{\phi}v_1 \geq \beta\bar{\phi}v_0 + (1 - \bar{\phi})v_0.$$

Inserting $\widehat{b}_{1,\kappa}$ from (42) and going through the same steps as in the Proof of Lemma 3 yields (38).

We know that the control transfer succeeds if and only if condition (38) holds. In that case, given that the bidder has full bargaining power, he acquires the controlling block at a price equal to the incumbent's valuation, (37). Moreover, when the incumbent sells shares to dispersed investors, they rationally anticipate the control transfer and thus are willing to pay up to $(1 - \beta)\bar{\phi}v_1$ for the minority stake. Overall, and as long as condition (38) holds, the incumbent's total payoff at the initial stage is therefore

$$\beta\bar{\phi}v_0 + (1 - \bar{\phi})v_0 + (1 - \beta)\bar{\phi}v_1. \tag{44}$$

Given that $v_1 > v_0$, the incumbent's total payoff decreases with β . On the other hand, condition (38) becomes tighter as β decreases. Consequently, the incumbent chooses the smallest value of $\beta \geq 0.5$ that is compatible with condition (38).

PROPOSITION 7: *The incumbent's optimal controlling block is*

$$\beta^* = \max \left\{ \frac{(1 - \bar{\phi})v_0 - A_1}{\bar{\phi}(v_1 - v_0)}, 0.5 \right\}. \tag{45}$$

Zingales (1995) also models the incumbent's choice of a controlling block in anticipation of a future control transfer, and he also assumes that the bidder is more efficient than the incumbent. However, Zingales assumes that the bidder is arbitrarily wealthy. In our model, if the bidder were sufficiently wealthy, the optimal controlling block would always be $\beta^* = 0.5$. In contrast, if the bidder is financially constrained, more precisely, if $A_1 < (1 - \bar{\phi})v_0 - \frac{\bar{\phi}}{2}(v_1 - v_0)$, the optimal controlling block is $\beta^* > 0.5$. By inspection, β^* decreases with $\bar{\phi}$.

COROLLARY 3: *The optimal controlling block is larger when legal investor protection is weak.*

This result is consistent with evidence by, for example, La Porta et al. (1998) and La Porta, Lopez-de-Silanes, and Shleifer (1999), who find that ownership is more concentrated in countries with weaker legal investor protection.

We conclude with a brief discussion of how our results might change if, instead of being subject to the MR, the bidder were subject to the EOR/MBR. We provide a formal analysis in the Internet Appendix.

Under the EOR/MBR, the bidder is obliged to make an offer to minority shareholders on the same terms as his offer to the incumbent. Accordingly, if the bidder pays a control premium to the incumbent, he must pay the same control premium also to minority shareholders. This has two effects, both of which make efficient sale-of-control transactions less likely. First, paying a control premium to minority shareholders reduces the bidder's profits and tightens his participation constraint. This effect whereby the EOR/MBR redistributes takeover gains from the bidder to minority shareholders is well known (e.g., Kahan (1993), Bebchuk (1994)). Second, and this effect is unique to our framework, any premium above the (pledgeable) security benefits must be financed

out of the bidder's internal funds. Thus, if the bidder is also forced to pay a control premium to minority shareholders, this tightens his budget constraint.

Besides the fact that efficient sale-of-control transactions are less likely to succeed, however, nothing changes. In particular, as shown in the Internet Appendix, all qualitative results from this section, that is, Proposition 6, Corollary 2, and Corollary 3, continue to hold if the bidder were instead subject to the EOR/MBR.

C. Cross-Border M&A

This section examines the case in which bidders come from different legal environments. Without loss of generality, we assume that $\bar{\phi}_1 > \bar{\phi}_2$. That is, bidder 1 comes from an environment with stronger legal investor protection than bidder 2. To isolate the effect of legal investor protection on the takeover outcome, we assume that both bidders have the same internal funds, A , and can create the same value, v .

In a typical cross-border M&A transaction, the target adopts the corporate governance structures, accounting standards, and disclosure practices of the acquirer (Rossi and Volpin (2004), Bris and Cabolis (2008), Chari, Ouimet, and Tesar (2010)). Hence, if bidder i wins the takeover contest, his private benefits are $(1 - \bar{\phi}_i)v$ while the security benefits accruing to all shareholders, including the bidder himself, are $\bar{\phi}_i v$. Note that, unlike in our previous analysis, private and security benefits are now inversely related: while bidder 1 generates higher security benefits, his private benefits are lower than bidder 2's. Also, note that both bidders now generate the same *total* (i.e., security plus private) benefits. From an efficiency standpoint, it is thus immaterial who wins the takeover contest. Hence, the question here is not whether efficient takeovers take place, but rather under what conditions bidders from countries with stronger legal investor protection can outbid their rivals from countries with weaker legal investor protection.

In principle, minority shareholder protection at the target firm may become *worse* if the acquirer comes from a country with weaker legal investor protection.²⁶ Empirically, however, this case seems less relevant. In the vast majority of cross-border M&A deals, the acquirer comes from a country with *stronger*, not weaker, legal investor protection (Rossi and Volpin (2004), Bris and Cabolis (2008), Chari, Ouimet, and Tesar (2010), Erel, Liao, and Weisbach (2012)), implying that “[o]n average, shareholder protection increases in the target company via the cross-border deal” (Rossi and Volpin (2004, p. 291)). To avoid this issue altogether, we assume that legal investor protection in the target's country, $\bar{\phi}_0$, is less than or equal to $\bar{\phi}_2$. In the special case in which $\bar{\phi}_0 = \bar{\phi}_2$, our model analyzes competition between a domestic bidder (bidder 2) and a

²⁶“The target almost always adopts the governance standards of the acquirers, *whether good or bad*” (Rossi and Volpin (2004, p. 300), italics added). Similarly, “the new law can be less protective than before, a type of legal reform that is unheard of in the literature” (Bris and Cabolis (2008, p. 606)).

foreign bidder (bidder 1). In all other cases, it analyzes competition between two foreign bidders.

The analysis is analogous to that in Section III except that $\bar{\phi}_i$ is bidder-specific while both A and v are identical across bidders. Accordingly, bidder i 's maximum offer is

$$\hat{b}_i = \bar{\phi}_i v + \min \{ (1 - \bar{\phi}_i)v, A \}. \tag{46}$$

PROPOSITION 8: *If $A < (1 - \bar{\phi}_2)v$, the bidder from the country with stronger legal investor protection wins the takeover contest. Otherwise, either of the two bidders may win the takeover contest.*

As both bidders create the same value, they have the same *willingness* to pay. Hence, the takeover outcome depends solely on their *ability* to pay. There are three cases.

If $A \geq (1 - \bar{\phi}_2)v$, neither bidder is financially constrained. As a result, both bidders can make a bid up to their full valuation of the target, v , which implies either bidder may win the takeover contest.

The second case, $(1 - \bar{\phi}_2)v > A \geq (1 - \bar{\phi}_1)v$, perhaps best illustrates the role of legal investor protection in takeover contests. While both bidders create the same value, v , bidder 1 generates more security benefits. Bidder 1 therefore has a higher outside funding capacity, allowing him to make a bid up to his full valuation, $\hat{b}_1 = v$. In contrast, bidder 2 can only make a bid up to $\hat{b}_2 = \bar{\phi}_2 v + A < v$. As a result, bidder 1 wins the takeover contest.

The third case, $A < (1 - \bar{\phi}_1)v$, is similar to the second, except that bidder 1 can no longer make a bid up to his full valuation. Consequently, both bidders can now only bid up to $\hat{b}_i = \bar{\phi}_i v + A$. However, as bidder 1 generates more security benefits, he can still outbid his rival, bidder 2.

We may again ask whether, conditional on the takeover succeeding, target shareholders benefit from stronger legal investor protection. In the first case, the winning bid is independent of $\bar{\phi}_i$. In the second and third cases, the winning bid is $b_1^* = \max\{\hat{b}_2, \bar{\phi}_1 v\}$, which is (weakly) increasing in the quality of legal investor protection in the *acquirer's* country, $\bar{\phi}_1$. Consistent with this result, Bris and Cabolis (2008) find that takeover premia in cross-border M&A deals are higher when legal investor protection in the acquirer's country is stronger than in the target's. Similarly, Rossi and Volpin (2004) find that takeover premia are higher in cross-border M&A deals compared to domestic M&A deals while the acquirer in a typical cross-border M&A deal is usually from a country with stronger legal investor protection.

VI. Firm-Level Governance

So far, we have focused on the legal environment as the main source of investor protection. However, firms can often improve on this minimum level. For instance, boards of directors or audit committees may curb controlling shareholders' self-serving behavior. In what follows, we assume that potential

bidders, by way of setting up such institutions, can credibly limit their private benefits extraction, thus effectively converting private benefits into pledgeable security benefits. Doing so is costly, however. Monitors, such as auditors and independent directors, require compensation for their activities. Such compensation is (realistically) paid out of the firm's own pocket. Accordingly, we assume that converting x units of private benefits into security benefits reduces firm value by γx , where $0 < \gamma < 1$. Security benefits are thus given by $\bar{\phi}(v - \gamma x) + x$, while private benefits amount to $(1 - \bar{\phi})(v - \gamma x) - x$. Starting from the level of private benefits associated with the prevailing level of legal investor protection, $(1 - \bar{\phi})v$, this implies that the maximum amount of private benefits that can be potentially converted is $x \leq (1 - \bar{\phi})(v - \gamma x)$ or, equivalently, $x \leq \frac{(1 - \bar{\phi})v}{1 + \gamma(1 - \bar{\phi})}$.

A. Single-Bidder Case

Stages 2 and 3 are analogous to our basic model. In particular, in stage 3, we have maximum dispersion, $\phi = \bar{\phi}$, while in stage 2 a successful tender offer must satisfy the free-rider condition

$$b \geq \bar{\phi}(v - \gamma x) + x. \quad (47)$$

Next, consider stage 1, where the bidder must choose the offer price b . In addition to satisfying the free-rider condition, (47), a successful tender offer must also satisfy the bidder's participation constraint

$$v - \gamma x - b - c \geq 0 \quad (48)$$

and budget constraint

$$A + \bar{\phi}(v - \gamma x) + x \geq b + c. \quad (49)$$

As usual, the optimal bid in the single-bidder case is such that the free-rider condition, (47), holds with equality. Hence, the bidder's budget constraint becomes

$$A \geq c, \quad (50)$$

while his participation constraints becomes

$$(1 - \bar{\phi})(v - \gamma x) - x \geq c. \quad (51)$$

The budget constraint (50) is identical to that in our basic model and is independent of legal investor protection but also of firm-level governance. Intuitively, once the free-rider condition is accounted for, the additional outside funding capacity due to firm-level governance does not relax the bidder's budget constraint, as the bid price, and thus the bidder's need for funds, increases in lock-step: $b = \bar{\phi}(v - \gamma x) + x$. Consequently, the only effect of firm-level governance is that it reduces the bidder's private benefits, thus tightening his participation constraint. Unlike in the basic model, however, this is now for *two* reasons. First, there is the direct, marginal reduction in private benefits equal to x .

Second, there is the inframarginal reduction of $(1 - \bar{\phi})\gamma x$ arising from the fact that the cost of firm-level governance is paid out of the firm's pocket.

Given that firm-level governance has no benefits, but only costs, the bidder optimally sets $x^* = 0$. As a result, the remaining analysis of the single-bidder case is isomorphic to our basic single-bidder model.

B. Bidding Competition

Firm-level governance *does* matter under effective competition among bidders. Stages 2 and 3 are analogous to our basic competition model, except that the free-rider condition in Lemma 2 is replaced by the requirement that $b \geq \bar{\phi}(v - \gamma x) + x$.

Consider next stage 1, and denote by \hat{b}_i the highest offer that bidder i is willing and able to make. That is, \hat{b}_i is the highest value of b_i satisfying the bidder's participation constraint

$$v_i - \gamma x_i - b_i - c \geq 0 \tag{52}$$

and budget constraint

$$\bar{\phi}(v_i - \gamma x_i) + x_i + A_i \geq b_i + c. \tag{53}$$

Hence, converting private benefits into security benefits ($x_i > 0$) relaxes the bidder's budget constraint but tightens his participation constraint.

Given (52) and (53), the highest offer that bidder i is willing and able to make is

$$\hat{b}_i = \bar{\phi}v_i + \min \{ (1 - \bar{\phi})v_i - \gamma x_i, A_i + x_i(1 - \bar{\phi}\gamma) \} - c. \tag{54}$$

The first term in brackets is decreasing in x_i while the second term is increasing in x_i . Accordingly, if the binding constraint is the bidder's participation constraint, that is, $(1 - \bar{\phi})v_i < A_i$, his maximum offer is given by $\hat{b}_i = v_i - \gamma x_i - c$, which implies he optimally sets $x_i^* = 0$. In contrast, if the binding constraint is the bidder's budget constraint, that is, $(1 - \bar{\phi})v_i \geq A_i$, his maximum offer is given by $\hat{b}_i = \bar{\phi}v_i + A_i + x_i(1 - \bar{\phi}\gamma) - c$. As this expression is increasing in x_i , the bidder optimally raises x_i until the second term in brackets is equal to the first.²⁷ Formally, this implies that x_i^* is given by

$$(1 - \bar{\phi})v_i - \gamma x_i^* = A_i + x_i^*(1 - \bar{\phi}\gamma).$$

LEMMA 11: *Bidder i's optimal choice of firm-level governance is given by*

$$x_i^* = \begin{cases} 0 & \text{if } (1 - \bar{\phi})v_i < A_i \\ \frac{(1 - \bar{\phi})v_i - A_i}{1 + \gamma(1 - \bar{\phi})} & \text{if } (1 - \bar{\phi})v_i \geq A_i \end{cases} \tag{55}$$

²⁷ If the bidder increased x_i beyond this point, the binding constraint in (54) would again become the participation constraint, implying the bidder's maximum offer would be decreasing in x_i . Accordingly, "optimal" means that x_i^* is the choice of firm-level governance that maximizes bidder i 's likelihood of winning the takeover contest.

Some comparative statics are of interest. Specifically, we have from (55) that $\frac{\partial x_i^*}{\partial \gamma} \leq 0$, $\frac{\partial x_i^*}{\partial A_i} \leq 0$, $\frac{\partial x_i^*}{\partial \bar{\phi}} \leq 0$, and $\frac{\partial x_i^*}{\partial v_i} \geq 0$. Moreover, the case in which $(1 - \bar{\phi})v_i \geq A_i$ holds becomes more likely when $\bar{\phi}$ and A_i are small and v_i is large.

COROLLARY 4: *Bidder i 's optimal choice of firm-level governance is decreasing in the cost of governance, the bidder's wealth, and the strength of legal investor protection, and increasing in the (gross) firm value created by the bidder.*

That x_i^* is decreasing in the cost of governance is intuitive. Also intuitive is that it is decreasing in the bidder's wealth. After all, the only purpose of firm-level governance in our model is that it relaxes the bidder's budget constraint. Indeed, if the bidder is sufficiently wealthy ($A_i > (1 - \bar{\phi})v_i$), his optimal choice of firm-level governance is $x_i^* = 0$. Similarly, it is intuitive that x_i^* is decreasing in the strength of legal investor protection. Indeed, legal investor protection and firm-level governance serve the same purpose in our model, but the latter is more costly from the firm's perspective. Finally, that x_i^* is increasing in firm value illustrates why empirical correlations between firm-level governance and firm value should be interpreted with caution. Indeed, in our model, the causality goes the other way: higher firm value implies that more private benefits can be converted into pledgeable security benefits by way of firm-level governance.

Inserting bidder i 's optimal choice of firm-level governance, (55), into his maximum offer function, (54), implies that the highest offer that bidder i is willing and able to make is

$$\widehat{b}_i = \min \left\{ v_i, \frac{v_i + \gamma A_i}{1 + \gamma(1 - \bar{\phi})} \right\} - c, \tag{56}$$

where $\widehat{b}_i = v_i - c$ if and only if $(1 - \bar{\phi})v_i \leq A_i$.

Accordingly, if bidder i is sufficiently wealthy ($A_i \geq v_i$), he is both willing and able to make a bid up to his full valuation of the target, $v_i - c$, regardless of the quality of legal investor protection. Moreover, in this case, we know from (55) that his optimal choice of firm-level governance is $x_i^* = 0$. In contrast, if $A_i < v_i$, there exists a critical value $\bar{\phi}' = \frac{v_i - A_i}{v_i}$ such that bidder i 's maximum offer is less than his full valuation if $\bar{\phi} < \bar{\phi}'$ and equal to his full valuation if $\bar{\phi} \geq \bar{\phi}'$. In the former case, bidder i 's maximum offer is increasing in $\bar{\phi}$ while his optimal choice of firm-level governance is $x_i^* > 0$ with $\frac{\partial x_i^*}{\partial \bar{\phi}} < 0$ and $x_i^* \rightarrow 0$ as $\bar{\phi} \rightarrow \bar{\phi}'$.

We can again compare under what conditions bidder 1's maximum offer, \widehat{b}_1 , exceeds bidder 2's maximum offer, \widehat{b}_2 .

LEMMA 12: *Bidder 1 wins the takeover contest if and only if*

$$A_1 \geq \min \left\{ (1 - \bar{\phi})v_2, A_2 \right\} - \frac{(v_1 - v_2)}{\gamma}. \tag{57}$$

As in our basic competition model, stronger legal investor protection promotes efficient takeover outcomes. Formally, if $A_1 \geq \min\{v_2, A_2\} - \frac{(v_1 - v_2)}{\gamma}$, the

takeover outcome is efficient for any value of $\bar{\phi}$. In all other cases, there exists a critical value $\bar{\phi}'' > 0$ such that the outcome is efficient if and only if $\bar{\phi} \geq \bar{\phi}''$.

These benefits of legal investor protection notwithstanding, allowing for firm-level governance may render legal investor protection redundant. To illustrate, consider the extreme case in which the costs of firm-level governance approach zero ($\gamma \rightarrow 0$). In this case, condition (57) implies that bidder 1 always wins the takeover contest, regardless of his private wealth or the quality of legal investor protection. Intuitively, the role of legal investor protection in our model is to provide bidders with pledgeable income, while that of private wealth is to make up for shortfalls in the bidders' pledgeable income. However, if bidders can costlessly convert private benefits into pledgeable security benefits, then neither legal investor protection nor the bidders' private wealth matter for efficiency.

More generally, allowing for firm-level governance, even if costly, makes it more likely that the target goes to the bidder who creates the most value. This is because higher value bidders have more private benefits that can be converted into security benefits, which gives their outside funding capacity greater boost.

PROPOSITION 9: *Under effective competition for the target, firm-level governance may improve the efficiency of the takeover outcome. The improvement is larger when legal investor protection is weak, when the costs of firm-level governance are low, and when the difference in firm values created by the bidders is large.*

To illustrate how firm-level governance can improve efficiency, suppose that $A_1 < v_2 < A_2$ (implying $A_1 < v_1$).²⁸ By condition (11), this implies that, without firm-level governance, bidder 1's maximum offer is $\hat{b}_1 = \bar{\phi}v_1 + \min\{(1 - \bar{\phi})v_1, A_1\} - c$, while bidder 2's is $\hat{b}_2 = v_2 - c$. Thus, by Lemma 3, bidder 1 loses the takeover contest if $\bar{\phi} < \frac{v_2 - A_1}{v_1}$.

Suppose now that we allow firm-level governance, thus allowing bidders to convert private benefits into pledgeable security benefits. By Lemma 11, bidder 2 optimally sets $x_2^* = 0$, implying that his maximum offer remains unchanged. In contrast, bidder 1 sets $x_1^* = 0$ for all $\bar{\phi} > \frac{v_1 - A_1}{v_1}$ but $x_1^* = \frac{(1 - \bar{\phi})v_1 - A_1}{1 + \gamma(1 - \bar{\phi})} > 0$ for all $\bar{\phi} \leq \frac{v_1 - A_1}{v_1}$. In the latter case, bidder 1's maximum offer increases to $\hat{b}_1 = \frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} - c$ (see equation (56)).

The upward shift of bidder 1's maximum offer function makes it more likely that bidder 1 succeeds, thereby improving efficiency. While the takeover outcome was, and still is, efficient if $\bar{\phi} \geq \frac{v_2 - A_1}{v_1}$, it was previously (i.e., without firm-level governance) inefficient if $\bar{\phi} < \frac{v_2 - A_1}{v_1}$. Introducing firm-level governance narrows the range of $\bar{\phi}$ for which the takeover outcome is inefficient. More precisely, by Lemma 12, bidder 1 loses the takeover contest if $\bar{\phi} < \frac{v_2 - v_1 + \gamma(v_2 - A_1)}{\gamma v_2}$, which is less than the respective threshold value without firm-level governance, $\frac{v_2 - A_1}{v_1}$. In fact, if the cost of firm-level governance is sufficiently small

²⁸ Any (nontrivial) claims made in this example are proven in Appendix B.

($\gamma \leq \frac{v_1 - v_2}{v_2 - A_1}$), bidder 1 always wins, irrespective of the quality of legal investor protection.

VII. Conclusion

This paper studies the effect of legal investor protection on the efficiency of the market for corporate control. Stronger legal investor protection limits the ease with which the bidder, once in control, can divert corporate resources as private benefits. This has two main implications. First, it reduces the bidder's profit, thus making efficient takeovers less likely. Second, it increases the bidder's pledgeable income and thus his outside funding capacity. However, absent effective bidding competition, this increased outside funding capacity does not relax the bidder's budget constraint, as the bid price increases in lockstep with his pledgeable income.

In contrast, under effective bidding competition, stronger legal investor protection, and the associated increase in the bidders' outside funding capacity, may improve the efficiency of the takeover outcome. In particular, by boosting bidders' ability to raise outside funds against the value they create, stronger legal investor protection makes it less likely that more efficient but less wealthy bidders are outbid by less efficient but wealthier rivals.

The presence of a binding budget constraint also provides a novel rationale for the one share–one vote rule. In our model, such a rule is socially optimal, as it maximizes the likelihood that the takeover outcome is determined by bidders' ability to create value rather than by their budget constraints. In addition, our model provides novel empirical implications relating the takeover outcome to, among other things, firm-level governance, margin requirements, asset tangibility, and block ownership.

Appendix A: Proofs

Proof of Lemma 2: For a bid to succeed in equilibrium, it must satisfy the free-rider condition, $b_i \geq \bar{\phi}v_i$. If no bid satisfies this condition, the only equilibrium outcome is that the takeover does not place. Suppose therefore that a bid satisfies $b_i \geq \bar{\phi}v_i$. If a target shareholder anticipates that the bid will succeed, tendering his shares is (at least) a weakly dominant strategy. Hence, an equilibrium exists in which a bid b_i succeeds if and only if $b_i \geq \bar{\phi}v_i$. Among all equilibria, the target shareholders' payoff is highest in those in which the highest bid succeeds. Q.E.D.

Proof of Lemma 3: For a bid to succeed under competition, it would a fortiori also have to succeed absent competition. By Lemma 1, this is true if and only if condition (12) holds. Moreover, in a Pareto-dominant equilibrium, bidder 1

wins the takeover contest only if $\widehat{b}_1 \geq \widehat{b}_2$. Using expression (11), this can be written as

$$\bar{\phi}v_1 + \min \{(1 - \bar{\phi})v_1, A_1\} - c \geq \bar{\phi}v_2 + \min \{(1 - \bar{\phi})v_2, A_2\} - c \tag{A1}$$

or

$$\min \{(1 - \bar{\phi})v_1, A_1\} \geq \min \{(1 - \bar{\phi})v_2, A_2\} - \bar{\phi}(v_1 - v_2). \tag{A2}$$

If $(1 - \bar{\phi})v_1 \leq A_1$, this condition always holds because

$$(1 - \bar{\phi})v_1 > (1 - \bar{\phi})v_2 - \bar{\phi}(v_1 - v_2) \geq \min \{(1 - \bar{\phi})v_2, A_2\} - \bar{\phi}(v_1 - v_2). \tag{A3}$$

Hence, condition (A.2) can be written as condition (13). Q.E.D.

Proof of Lemma 8: Suppose bidder i bids b_i for voting shares and b_i^0 for nonvoting shares. Who wins the takeover contest is determined solely by the bids for voting shares. Hence, in a Pareto-dominant equilibrium (for the voting shareholders), the winning bid is the highest among those satisfying $b_i \geq \bar{\phi}v_i$, if any. If bidder i fails to gain control, his bid for nonvoting shares is irrelevant. (Bids for nonvoting shares are conditional upon gaining control.) Conversely, if bidder i gains control, nonvoting shareholders tender only if $b_i^0 \geq \bar{\phi}v_i$. In this case, the winning bidder’s payoff is

$$\alpha(\bar{\phi}v_i - b_i) + (1 - \alpha)(\bar{\phi}v_i - b_i^0) + (1 - \bar{\phi})v_i. \tag{A4}$$

Given the requirement that $b_i^0 \geq \bar{\phi}v_i$, expression (A4) is maximized for $b_i^0 = \bar{\phi}v_i$, in which case it becomes

$$\alpha(\bar{\phi}v_i - b_i) + (1 - \bar{\phi})v_i, \tag{A5}$$

which is the same as if bidder i did not bid for nonvoting shares. Consequently, bidder i is indifferent between bidding and not bidding for nonvoting shares: he makes zero profit on these shares, and they do not help him gain control. Q.E.D.

Proof of Lemma 10: The proof is analogous to that of Lemma 3 with $c = 0$ and expression (11) replaced by (36) for the bidder and by

$$\widehat{b}_0 = \bar{\phi}v_0 + \frac{1}{\beta} \cdot (1 - \bar{\phi})v_0 \tag{A6}$$

for the incumbent. Q.E.D.

Proof of Proposition 9: The result follows from comparing condition (57) with the corresponding requirement from Section III, condition (13), noting that

$$\frac{v_1 - v_2}{\gamma} > v_1 - v_2 > \bar{\phi}(v_1 - v_2) \tag{A7}$$

for all $\gamma < 1$ and $\bar{\phi} < 1$ and that $(\frac{1}{\gamma} - \bar{\phi})(v_1 - v_2)$ is decreasing in γ and $\bar{\phi}$ and increasing in $v_1 - v_2$. Q.E.D.

Appendix B: Example following Proposition 9

Recall that $A_1 < v_2 < A_2$ (implying that $A_1 < v_1$). The first unproven claim is that raising bidder 1's maximum offer from $\widehat{b}_1 = \bar{\phi}v_1 + A_1 - c$ to $\widehat{b}_1 = \frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} - c$ for all $\bar{\phi} \leq \frac{v_1 - A_1}{v_1}$ narrows the range of $\bar{\phi}$ for which the takeover outcome is inefficient, that is, where bidder 1 loses. Given that bidder 2's maximum offer was, and still is, $\widehat{b}_2 = v_2 - c$, the takeover outcome was previously (i.e., without firm-level governance) inefficient if $\bar{\phi}v_1 + A_1 < v_2$ or $\bar{\phi} < \frac{v_2 - A_1}{v_1}$. In contrast, it is now inefficient if $\frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} < v_2$ or $\bar{\phi} < \frac{v_2 - v_1 + \gamma(v_2 - A_1)}{\gamma v_2}$. To prove that $\frac{v_2 - v_1 + \gamma(v_2 - A_1)}{\gamma v_2} < \frac{v_2 - A_1}{v_1}$, it suffices to show that $\frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})}$ lies strictly above $\bar{\phi}v_1 + A_1$ for all $\bar{\phi} < \frac{v_1 - A_1}{v_1}$. To see this, note that $\frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} = \bar{\phi}v_1 + A_1$ at $\bar{\phi} = \frac{v_1 - A_1}{v_1}$ with derivative $\left. \frac{\partial}{\partial \bar{\phi}} \frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} \right|_{\bar{\phi} = \frac{v_1 - A_1}{v_1}} = \gamma v_1 < v_1$. That $\frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})}$ is strictly increasing and convex in $\bar{\phi}$ completes the proof.

The second unproven claim is that, if $\gamma \leq \frac{v_1 - v_2}{v_2 - A_1}$, bidder 1 wins the takeover contest for all $\bar{\phi}$. To see this, recall that $\widehat{b}_1 = \frac{v_1 + \gamma A_1}{1 + \gamma(1 - \bar{\phi})} - c$ is strictly increasing in $\bar{\phi}$. Hence, we have that $\widehat{b}_1 \geq \widehat{b}_2 = v_2 - c$ for all $\bar{\phi}$ if $\frac{v_1 + \gamma A_1}{1 + \gamma} \geq v_2$ or $\gamma \leq \frac{v_1 - v_2}{v_2 - A_1}$. Indeed, if $\frac{A_1 + v_1}{2} \geq v_2$, we have that $\frac{v_1 - v_2}{v_2 - A_1} \geq 1$. In this latter case, bidder 1 wins the takeover contest for all $\bar{\phi}$ even as $\gamma \rightarrow 1$.
